Who We Are/ Acknowledgments

Golf Course Superintendents Association of America

The Golf Course Superintendents Association of America (GCSAA) is the professional association for the men and women who manage and maintain the game's most valuable resource — the golf course. Today, GCSAA and its members are recognized by the golf industry as one of the key contributors in elevating the game and business to its current state.

Since 1926, GCSAA has been the top professional association for the men and women who manage golf courses in the United States and worldwide. From its headquarters in Lawrence, Kansas, the association provides education, information and representation to more than 17,000 members in more than 72 countries. GCSAA's mission is to serve its members, advance their profession and enhance the enjoyment, growth and vitality of the game of golf.

Environmental Institute for Golf

The Environmental Institute for Golf (EIFG) fosters sustainability by providing funding for research grants, education programs, scholarships and awareness of golf's environmental efforts. Founded in 1955 as the GCSAA Scholarship & Research Fund for the Golf Course Superintendents Association of America, the EIFG serves as the association's philanthropic organization. The EIFG relies on the support of many individuals and organizations to fund programs to advance stewardship on golf courses in the areas of research, scholarships, education, and advocacy. The results from these activities, conducted by GCSAA, are used to position golf courses as properly managed landscapes that contribute to the greater good of their communities. Supporters of the EIFG know they are fostering programs and initiatives that will benefit the game and its environment for years to come.

United States Golf Association

The United States Golf Association (USGA) provides governance for the game of golf, conducts the U.S. Open, U.S. Women's Open and U.S. Senior Open as well as 10 national amateur championships, two state team championships and international

matches, and celebrates the history of the game of golf. The USGA establishes equipment standards, administers the Rules of Golf and Rules of Amateur Status, maintains the USGA Handicap System and Course Rating System, and is one of the world's foremost authorities on research, development and support of sustainable golf course management practices.

Acknowledgments

The GCSAA and EIFG wish to thank the **University of Florida**, Institute of Food and Agricultural Sciences, faculty, Dr. J. Bryan Unruh, Dr. Travis Shaddox, Dr. Jason Kruse, and Mr. Don Rainey, who worked on this project, providing their knowledge and expertise to help the golf course industry; the **USGA** for their grant to fund this important project; the **volunteers who served on the task group** to review BMP and provide technical assistance; and the **Florida Department of Environmental Protection** for permission to copy its publication, "Best Management Practices for the Enhancement of Environmental Quality on Florida Golf Courses

Additional Acknowledgement

The development of the Best Management Practices for New England Golf Courses was made possible by the New England Regional Turfgrass Foundation, superintendents across the region, and scientists from the University of Connecticut and the University of Massachusetts. The following representatives to the BMP committee provided the leadership, expertise, and commitment necessary to develop these BMPs specifically for New England:

- Committee Chair Peter Gorman, Connecticut Association of Golf Course Superintendents
- Rick Lawlor, CGCS, Golf Course Superintendents Association of Cape Cod
- Peter Rappoccio Jr. CGCS, Golf Course Superintendents Association of New England
- Robert Searle, Maine Golf Course Superintendents Association
- Dave Ousterhout, New Hampshire Golf Course Superintendents Association
- Drew Cummins, Rhode Island Golf Course Superintendents Association
- Kevin Komer, Vermont Golf Course Superintendents Association
- John Inguagiato, Ph.D, University of Connecticut
- Mary Owen, University of Massachusetts
- Kevin Doyle, Golf Course Superintendents Association of America
- Jim Skorulski, United States Golf Association

In creating these guidelines, a number of experts contributed their expertise, writing, revising, and reviewing drafts during the development process. The BMP is grateful to the following authors for providing their deep knowledge of golf course management to the development of this document:

- Mark Mungeam, Mungeam Cornish Golf Design, Inc.
- Robert Healey, Irrigation and Management Services
- Michelle DaCosta, Ph.D., University of Massachusetts
- Sarah W. Stearns, PWS, Beals + Thomas
- Matthew Cote, PE, Beals + Thomas
- Karl Guillard, Ph.D., University of Connecticut
- John Inguagiato, Ph.D. University of Connecticut
- Steven Rackliffe, University of Connecticut
- Jason Henderson, Ph.D., University of Connecticut
- Mary Owen, University of Massachusetts
- Patricia Vittum, Ph.D., University of Massachusetts
- Victoria Wallace, University of Connecticut
- Alyssa Siegel-Miles, University of Connecticut Extension
- Amelia R. Gulkis, Ensave, Inc.

The development of the Best Management Practices for Vermont Golf Courses was made possible by the New England Regional Turfgrass Foundation, superintendents

across the region, and scientists from the University of Vermont, University of Connecticut and the University of Massachusetts. The following representatives to the BMP committee provided the leadership, expertise, and commitment necessary to develop these BMPs specifically for Vermont:

- Alden Maddocks, Ekwanok Country Club
- Kevin Komer, The Mountain Course at Spruce Peak
- Michael O'Connor, GreenSpace Environmental & Turf Services
- Ken Lallier, Quechee Club
- Larry Keefe, Williston Golf Club
- Matthew Wood, Vermont Agency of Agriculture
- Geunhwa Jung, Ph.D., University of Massachusetts

Introduction

Vermont's golf course superintendents are dedicated to protecting the region's natural resources. As a demonstration of this commitment, superintendents have partnered with the New England Regional Turfgrass Foundation, scientists at the University of Connecticut and University of Massachusetts, and industry representatives to develop and document best management practices (BMPs) for golf course management. These research-based, voluntary guidelines have been developed specifically for Vermont's golf courses. These guidelines not only protect natural resources, they also afford the opportunity for superintendents to be recognized as environmental stewards by club members, the community at large, and state officials.

Best Management Practices

BMPs are methods or techniques found to be the most effective and practical means of achieving an objective, such as preventing deleterious water quality impacts or reducing pesticide usage. The turfgrass industry recognizes the importance of protecting surface and groundwater quality, thus the majority of BMPs in this document relate to water. Many BMPs protect water quality by reducing nonpoint source pollution (such as nutrients and pesticides in stormwater runoff), stormwater volume, and peak flow. Through retention, infiltration, filtering, and biological and chemical actions, any negative effects of golf courses on surface and groundwater resources can be prevented or minimized. In fact, several studies have shown that implementing BMPs can improve water quality as it traverses golf course properties. Many BMPs also can be used to conserve water and to prepare for water use restrictions that may be imposed in times of extended drought.

Pollution Prevention

Best management practices reduce the potential for sedimentation, runoff, leaching, and drift -- the mechanisms that can transport contaminants and impact water quality. For example, bare ground is much more likely to erode than areas with established turf. Therefore, following grow-in BMPs during course construction or renovation to quickly establish dense turf ground cover helps minimize erosion potential. Maintaining vegetated areas, such as filter strips and buffers, to slow down stormwater, allows infiltration and uptake and is another key BMP. Pesticide BMPs help superintendents follow state and federal regulations related to the storage, handling, transport, and use of pesticides, preventing point source pollution and minimizing the potential for nonpoint source pollution from these chemicals.

Understanding site characteristics is another key to preventing pollution. Some areas, such as the Green and White Mountains and their foothills have steeper slopes than the coastal plains and are therefore more prone to runoff. The areas of the region that have a shallow depth to water table are more prone to leaching. Understanding how BMPs can be used in concert with an understanding of site-specific characteristics helps to prevent conveyance of contaminants to surface and groundwaters.

Water Conservation

Water is a fundamental element for physiological processes in turf such as photosynthesis, transpiration, and cooling, as well as for the diffusion and transport of soil nutrients. Turf quality and performance depend on an adequate supply of water through either precipitation or supplemental irrigation. Too little water induces drought stress and weakens plants, while too much causes anaerobic conditions that stunt plant growth and promote disease. Excessive water can also lead to runoff or leaching of nutrients and pesticides into groundwater and surface water. Proper irrigation scheduling, careful selection of turfgrass species, and incorporation of cultural practices that increase the water-holding capacity of soil are addressed through these BMPs, as are considerations in the design, construction, and maintenance of irrigation systems.

Pollinators

Protecting bees and other pollinators is important to the sustainability of agriculture. Minimizing the impact of pesticides on bees, other pollinators, and beneficial arthropods is addressed in this document in two ways: providing specific guidance for pesticide applicators and promoting the use of integrated pest management (IPM) methods to reduce pesticide usage and minimize the potential of exposure. Superintendents can also directly support healthy pollinator populations by providing and enhancing habitat for pollinator species and by supplying food sources and nesting sites and materials.

State BMPs

Each New England state (Maine, Vermont, New Hampshire, Massachusetts, Rhode Island, and Connecticut) will be using these regional BMP guidelines to develop state-specific BMPs in 2020. Each state's BMP steering committee will review the regional guidelines, add regulatory information specific to that state, and publish their state BMPs.

Individual Facility BMPs

As each New England state finalizes its state-specific BMP guidelines, superintendents in that state will be asked to create their own facility BMP. To adapt BMPs to an individual facility, superintendents should assess their individual site, consider their available resources (such as budget), and understand that implementing BMPs will be an ongoing process that can be undertaken over time.

Besides contributing to natural resources stewardship, incentives for golf courses to create a facility BMP plan and to implement BMPs include the following:

- Cost savings associated with applying less fertilizer and pesticide.
- Potential for more efficiently allocating resources by identifying management zones.

- Cost savings associated with more efficient irrigation and other water conservation efforts by reducing electricity needs and equipment usage.
- Recognition by club members and the community at large for environmental stewardship.

Because of limitations, such as budget, staff, clientele expectations, and management decisions, not all golf courses can achieve all of the best practices. Superintendents should understand that implementing BMPs will be a process that can be undertaken over time. In addition, making even small changes that meet the goals of BMPs can easily be achieved. For example, while a sophisticated wash water recycling system may be too expensive for many facilities, blowing clippings off mowers onto a grass surface can markedly reduce the amount of nitrogen and phosphorus in clippings that end up in wash water.

Conclusion

This document was developed using the latest science-based information and sources. Using BMP guidelines, superintendents will have ready access to the most recent scientific information that can be used to inform their management activities.

Planning, Design and Construction

Preface

The development of a new golf course or the renovation of an existing facility requires consideration of numerous environmental, economic and site suitability factors. These must be carefully considered during each step of planning, design, and construction to ensure that the project is viable, sustainable, and ecologically sensitive (Table 1-1). The thoughtful use of best management practices during planning, design and construction are important to a successful result. Use of BMPs should not be considered a regulatory burden. Instead, they improve and protect natural resources for current and future generations of golfers and citizens. Furthermore, when facilities are designed and constructed to maximize sustainability, it positively impacts other topics in this document, such as maintenance operations, landscaping, and energy efficiency.

Planning

Figure 1-1. With the original design too close to a wetland (left), the committee decided to create a short game area on a different section of the club's land (right)

The implementation of a golf course project typically benefits from the use of professional consultants familiar with similar requirements. The consultants needed depends on the scope and complexity of the proposed work and the constraints present at the project site. Most projects commence with the hiring of a qualified golf course architect, a civil engineer and an environmental consultant. For most renovation projects, this may be the extent of consultants required for planning.

The first step in planning is development of an accurate existing conditions plan identifying property boundaries, topography, vegetation limits, roads, wetlands and other jurisdictional areas. A good base map is a critical tool in planning a project to avoid negative environmental impacts and to determine the feasibility of achieving

project goals. The development of a constraints plan, along with identification of a suitable water source (for new courses) may determine that a site is unsuitable for the intended golf project before expensive planning and permitting begins.

Once the suitability is confirmed through generation of preliminary concept plans and cost estimates, a team is generally assembled to guide the project. The golf course architect and civil engineer may be helpful in assembling the permitting team. Professional, experienced judgement is crucial when implementing BMPs in the planning, design and construction phases of the project. An experienced golf course superintendent is integral to the planning process for any golf project. For course renovation projects, with their extensive knowledge of the site, they can assist in determining the most suitable design and can inform the design team of issues that may impact maintenance of the course or player enjoyment of the facility. The superintendent's knowledge of the BMPs and their direct participation in planning and construction greatly affect the success of the project.

Table 1. Overview of the steps involved in golf course planning, design, and construction

Planning	
Step	Description
<i>Assemble Team</i>	The team should include, but not be limited to, a golf course architect, golf course superintendent, clubhouse architect, irrigation engineer, environmental engineer, energy analyst, economic consultant, civil engineer, soil scientist, golf course builder, biologist or ecologist, and a legal team. For new golf courses, a licensed golf course designer is required by law to guide the site analysis process.
<i>Define Objectives</i>	Identify realistic goals, formulate a timeline, etc.
<i>Conduct a Feasibility Study</i>	Evaluate finances, environmental issues, water availability and sources, and energy, materials, and labor needs. Identify applicable government regulations.
<i>Select and Analyze Site</i>	Site should meet project goals and expectations. Identify all strengths and weakness of each potential site. During site selection, any site constraints, such as the presence of listed species, valuable habitat, or invasive species should be identified
Design	
<i>Retain a Project Manager/Superintendent</i>	This person is responsible for integrating sustainable practices in the development, maintenance, and operation of the course.
<i>Design the Course</i>	Existing native landscapes should remain intact as much as possible. Consider supplemental native vegetation to enhance existing vegetation alongside lengthy fairways and

	out-of-play areas. Nuisance, invasive, and exotic plants should be removed and replaced with native species adapted to the area.
	Structural BMPs: Incorporate structural BMPs into the design plan, identifying opportunities to detain stormwater and to improve water quality through stormwater volume reduction, filtering, and biological and chemical processes.
	Greens: Should have plenty of sunlight and be well drained. Greens should be big enough to have several hole locations that can handle expected traffic. Root zone material should be selected with United States Golf Association (USGA) specifications in mind, as published in A Guide to Constructing The USGA Putting Green . Physical testing of these sands by an accredited laboratory prior to use is recommended.
	Grass Selection: Species should be selected based on climate, environmental, and site conditions and species adaptability to those conditions, including disease resistance, drought tolerance, spring greenup, and traffic tolerance.
	Bunkers: The number and size of bunkers depend on considerations, such as the resources available for daily maintenance. For each bunker consider: <ul style="list-style-type: none"> • The need for drainage • Entry/exit points and how these will affect wear-and-tear patterns • The proper color, size and shape of bunker sands to meet needs
	Vegetative Filters: Vegetative filters (conservation buffers, vegetated filter strips, swales, etc.) can be used throughout the golf course to act as natural biofilters to reduce stormwater flow and pollutant load. Turf areas are also effective filters.
<i>Design Irrigation System</i>	Hire a professional irrigation architect, if possible, to design the irrigation system. Keep in mind the different water needs of greens, tees, fairways, roughs, and native areas. Consider the topography, prevalent wind speeds, and wind direction when spacing the heads. Choose the most efficient type of irrigation system considering available resources.
Construction	
<i>Select Qualified Contractors</i>	Use only qualified contractors who are experienced in the special requirements of golf course construction, such as members of the Golf Course Builders Association of America .

<i>Safeguard Environment</i>	Follow all design phase plans and environmental laws. Soil stabilization techniques should be rigorously employed to maximize sediment control and minimize soil erosion. Temporary construction compounds and pathways should be built in a manner that reduces environmental impacts. Prevent the spread of invasive species.
<i>Install Irrigation System</i>	Installation should consider the need to move equipment and bury pipe while maintaining the original soil surface grade to minimize the potential for erosion.
<i>Establish Turfgrass</i>	Turfgrass establishment methods and timing should allow for the most efficient progress of work, while optimizing resources and preventing erosion from bare soils before grass is established.

Vermont's Act 250

Act 250 is Vermont's land use and development law, enacted in 1970 at a time when Vermont was undergoing significant development pressure. The law provides a public, quasi-judicial process for reviewing and managing the environmental, social and fiscal consequences of major subdivisions and developments in Vermont. It assures that larger developments compliment Vermont's unique landscape, economy and community needs. One of the strengths of Act 250 is the access it provides to neighbors and other interested parties to participate in the development review process. Applicants often work with neighbors, municipalities, state agencies and other interested groups to address concerns raised by a proposed development, resolving issues and mitigating impacts before a permit application is filed. An Act 250 permit is required for certain kinds of development and subdivision activity — such as commercial projects on more than 10 acres (if the town has permanent zoning and subdivision regulations) or on more than one acre (if it does not) or the subdivision of 10 lots or more in a five year period. Act 250 jurisdictional categories are summarized in the publication [Act 250 Jurisdiction](#) and more fully described in the [Act 250 Statute](#) and the [Act 250 Rules](#). To determine whether you need an Act 250 permit, contact your [Act 250 District Coordinator](#). Prior Jurisdictional Opinions of the District Coordinators are listed on the [Jurisdictional Opinions](#) page.

Water Sources

Golf courses are perceived as using a lot of water. Many states regulate the amount of water a course can use for irrigation, and the source of that water. Regulators may require that the course utilize degraded water, or limit the amount of water taken from wells, streams or lakes. For some courses that lack their own supply, the only option is to purchase costly municipal water. These requirements can severely impact the economic feasibility of a golf project. For more information on water sources, see the Irrigation chapter.

Wetlands and Streams

Wetlands are areas where water covers the soil or is present either at or near the surface of the soil all year or for varying periods of time during the year, including during the growing season. The boundaries and buffer zones of any wetlands, vernal pools, coastal zones, water bodies, intermittent streams and rivers should be identified, flagged and mapped in accordance with local, state and federal regulations by a qualified specialist. Regulated activities, such as draining, dredging, clearing and filling within or in proximity to wetlands, streams, or rivers, require permits from the appropriate regulating authorities. A professional consultant should be utilized to determine permitting needs and provide design assistance to reduce impacts. In some cases, the scope of a project can be changed to eliminate work in a regulated area. If not, the design may be altered to reduce impacts or generate other environmental improvements.

Floodplains

Golf courses can be a compatible use of floodplain zones, depending on the frequency and severity of flooding. When persistent floods could result in frequent course closures, turf loss and/or significant sediment removal and bunker repair, then use for golf may not be sustainable without improvements.

Listed Species and Habitats

In addition to identifying wetlands and floodplains before intensive planning, the absence of any listed species or habitats of concern should be verified with the appropriate state agency. The presence of either listed species or habitats of concern within the site boundaries or in proximity to the project site could limit the goals and objectives for the project.

Best Management Practices for Planning

- Assemble a qualified team with expertise in golf development and environmental permitting.
- Determine objectives and complete a feasibility study of the project.
- Select an appropriate site that is capable of achieving the needs of stakeholders and identify strengths and weakness of the selected site.
- Have a qualified specialist accurately identify wetland boundaries.
- Identify any listed species or habitat of concern on the site.
- Determine if your project needs an Act 250 permit.

Turfgrass Establishment

Turfgrass establishment is a unique phase in turfgrass growth and requires greater quantities of water and nutrients than maintaining established turfgrasses. To this end, the establishment phase should be considered carefully to minimize environmental risk.

Selection of turfgrass species or cultivar is one of the most important decisions a manager can make to ensure a healthy turfgrass stand. Prior to establishing turf, turfgrass managers should select grass species and cultivars based on the existing site conditions and the intended use of the turf, as described in the Cultural Practices chapter.

Seedbed Preparation

Proper seedbed site preparation can help avoid long-term problems, such as weed encroachment, diseases, and drought susceptibility. Debris should be removed that could hinder root growth and limit access to water and nutrients. Any drainage issues should be corrected through grading and installation of drainage technologies.

Sodding

Most grasses can be sodded during any time of the year. Sod should be topdressed to fill in the gaps between the pieces to speed establishment and create a smoother surface. During dry weather (summer or winter), light and frequent irrigation is required until the sod takes root. Check for rooting by lightly pulling the corner of the sod. Irrigation frequency can be reduced when the sod cannot be pulled from the soil surface.

Seeding

New England's cool-season turfgrass species (bluegrass, fescues, and ryegrass) should be seeded in late summer, except creeping bentgrass. This timing is generally ideal because soils are warm, nights are cool, and disease and weed pressure are reduced. However, research at the University of Connecticut has found July or early-August to be optimal for seeding creeping bentgrass to minimize annual bluegrass competition which typically germinates during late-summer and fall. Cool-season grasses can also be dormant seeded in late fall through the winter.

[Click here](#), to view **Dr. Sid Bosworth's "Fertilization and Nutrient Management Guidelines for Golf Turf in Vermont."** This guideline will give you an overview of nutrient recommendations for turfgrass establishment.

Cool-season species can be seeded in the spring, especially following winterkill. However, for any spring seeding, pre-emergence herbicides should be used to vastly improve the success of grow-in. Without a pre-emergence herbicide, spring seeding success is significantly reduced because of the summer annual weed pressure. Herbicide labels should be reviewed to ensure that the product is labeled for use during establishment. A drop-type spreader should be used for uniform seed dispersal. Lightly raking the soil or using specialized "slit seeders" improves seed-to-soil contact.

During grow-in and establishment, more water is required than for established stands. Until the sod begins to root down or the seedlings start to establish, water should be

applied lightly and frequently. The goal is to keep the surface moist until germination. Irrigation frequency should then be reduced, though the amount of water applied should be slightly increased until the first mowing. Turfgrasses with relatively large seeds (i.e., tall fescue, perennial ryegrass, and fine fescue) generally need fewer irrigation events during establishment than finer-textured seeds (i.e., Kentucky bluegrass and creeping bentgrass).

In phosphorus-deficient soils, phosphorous should be applied to the soil before seeding or sodding at a rate ranging from 0.5 to 1.5 lbs P_2O_5 per 1,000 square feet (22 to 65 lbs P_2O_5 per acre). A follow-up application of phosphorus fertilizer may be required four to eight weeks after seedling germination or sodding. A second application is justified if the turf has symptoms of phosphorus deficiency (such as purple-blue color, thin canopy, poor nitrogen response). Soils with a pH greater than 7.5 are also at greatest risk of phosphorus deficiency during establishment. Therefore, higher rates and a second application of phosphorus fertilizer are recommended for high pH soils.

Nitrogen (N) management is essential during establishment. For highly maintained turf stands or turf growing on sand or sand-based soils, soluble sources of N fertilizer should be applied every 7 to 14 days. Fertilizer applications should continue until the turf canopy has achieved 100% cover. Single application rates should not exceed 0.5 lbs of N per 1,000 square feet. Slow-release nitrogen sources can also benefit establishment regardless of soil type. Higher N application rates may be used with products containing more slow-release nitrogen. Fertilizers with 50% quick-release and 50% slow-release N provide uniform nitrogen release for a period of 6 to 10 weeks, depending on the formulation.

Micronutrient fertilizers can also be beneficial during establishment, especially on sandy or high pH soils. Nutrients such as iron and manganese can sometimes be limiting in these soil conditions. The recommendations found in soil test results are for established turfgrass. For establishing a new stand, these recommendations are not as beneficial. Instead, deficiencies can be diagnosed through small applications of fertilizer to a section of the turf. Lack of a response indicates that the nutrient is not limiting and that application to the entire area is not warranted.

For a majority of turfgrass areas, mowing should begin as soon as the turf height reaches the desired mowing height for that area. An exception may be putting greens. While some managers will start mowing to standard putting green heights immediately (0.15" or less), most managers start mowing at 0.4" and slowly reduce the height of cut as the stand matures. Regular mowing promotes new tiller formation and stimulates the transition from juvenile to mature plants.

Figure 1-2. The tee was sodded, while the tee surround was hydro seeded to help prevent erosion and stabilize the soil, during the winter months.

Best Management Practices for Turfgrass Establishment

- The area to be established should be properly prepared and cleared of pests (e.g. weeds and pathogens).
- Select cultivars that are adapted to the desired use, taking note of disease resistance, drought, traffic, and shade tolerance, and other traits such as texture and color.
- Ensure erosion and sediment control devices are in place and properly maintained.
- Use mulch (e.g., hydromulch, loose straw from a clean source, straw mats) for soil stabilization.
- Prepare seed/sod bed to maximize success.
- Fill gaps in sod seams with soil or sand to provide a uniform surface.
- Use selective pre-emergence herbicides to reduce weed competition and improve the chance of success with seeding establishment during the spring.
- Apply a fertilizer containing phosphorus at seeding. An additional application should be applied if turf displays symptoms of phosphorus deficiency.

- Nitrogen and sufficient water are essential during establishment. Light and frequent applications of nutrients are most desirable, unless a slow-release nitrogen source is used.
- Mow turf to the desired mowing height as soon as practical to promote density and maturation. Never remove more than one-third of the turf leaf at mowing.

Design

It is important to establish clear and achievable goals and objectives at the commencement of any proposed project. The professional team can assist the course owner or developer in refining the goals and objectives by providing concept plans and cost estimates for the work in the preliminary phase of design. This information helps to determine what changes are appropriate for the site, the financial feasibility of the project and the anticipated schedule for implementation. Although the process of developing goals and objectives varies depending on the complexity of the proposed work, projects are most successful when a clear scope of work is defined and thoughtfully implemented.

A good design meets the needs of the stakeholders, protects the location's environmental resources, and is economically sustainable. The design should address a number of site issues, such as the ones discussed below.

Environmental Impacts

The design should avoid or minimize impacts to sensitive environmental issues that may have been identified during the site review and preliminary planning phase. When impacts are unavoidable, the design should identify the scope of the impact and address how future use and maintenance of the course will be undertaken to lessen negative impacts.

Wetlands and Streams

When incorporated into a golf course design (or renovation), wetlands should be maintained as preserves and separated from managed turf areas with native vegetation buffers. Wetlands should be managed as natural areas, with their habitat structure and existing hydrology fully protected from excessive runoff discharges, de-watering effects from irrigation sources and from nutrients or pesticides used during golf course maintenance. The replacement of failing culverts or the installation of raised cart paths or boardwalks provides an opportunity to upgrade stream crossings and improve streamflow, wetlands and buffer areas, and provide water quality or wildlife habitat protection benefits.

Constructed Wetlands

Constructed aquatic ecosystems simulate the role of natural wetlands with respect to water purification. and may be permitted to be an integral part of the stormwater

management system. Like natural wetlands, they feature poorly drained soils and rooted emergent hydrophytes, which simulate the role of natural wetlands in water purification. These structures efficiently remove certain pollutants (nitrogen, phosphorus, metals, sediment, and other suspended solids) and can treat wastewater, such as discharges from equipment wash pads before the water enters streams, natural wetlands, or other surface water. Once these areas are constructed, however, they are considered wetlands and regulated as such.

Floodplains

Any planned substantial disturbance to a floodplain, including clearing and grading, generally requires an engineering analysis to demonstrate minimal impact on the base flood elevation in accordance with local ordinances. Depending on the complexity of the encroachment, this analysis may be as simple as a comparison of cut and fill quantities within the floodplain or as complex as a detailed floodplain model of the entire watershed. A complex analysis may require a Federal Emergency Management Agency (FEMA) review along with potential revision to the floodplain mapping.

Floodplain restoration is the reestablishment of natural water systems to help mitigate flooding and control stormwater. During the planning and design phase, floodplain restoration activities can address vertical and lateral stream migration, which causes unstable banks, flooding, reductions in groundwater recharge, and high sediment and nutrient loads. When incorporating floodplain restoration into the course design or renovation, land use decisions and engineering standards must be based on the latest research science available. Where appropriate and if land is available, installing or enhancing stream buffers may also help restore or enhance natural water flows and flooding controls as well as providing wildlife habitat.

Stormwater Management

Although golf courses are typically large properties ranging from 60 to 200 acres, they are just one link in a stormwater management chain. Generally, a quantity of stormwater enters the golf course area, supplemented by what falls on the golf course proper, and then the stormwater leaves the golf course. Therefore, golf courses are realistically capable of having only a small impact on major stormwater flow. That impact should be to add only small increments of water to the stormwater flow over a given period of time. Engineers call this function “detention.”

When golf courses are designed, their drainage capability concept is guided by an average rainfall event of a given frequency. For example, a golf course drainage system is typically designed to detain a two- or five-year rain event. In other words, when that rain event happens, the golf course will be able to be reasonably drained in a matter of hours, as excess water not absorbed by the soil flows through the drainage system, is temporarily held, and finally leaves the property. In some instances, golf courses and other recreational facilities are mandated to be designed to handle a 20-, 50- or 100-year rain event, which means the golf course must detain more water for perhaps a

longer period of time. The ability to detain large amounts of water requires accurate engineering and extensive construction to prevent physical or financial damage to the facility.

BMPs are intended to prolong the detention process as long as practical, harvest as much of the stormwater in surface or underground storage as reasonable, and to improve the quality of water leaving the property when possible. Methods of stormwater management include infiltration chambers that allow water to better enter the ground and recharge aquifers, retention basins that slow the flow of water off the property during heavy rain events while also trapping sediments, and installation of swales with check dams to slow runoff.

Vermont Stormwater Program/Permit

The management of stormwater runoff is at once a simple concept and a complex problem. Precipitation runs off impervious surfaces rather than infiltrating into the soil. The cumulative impact resulting from the increased frequency, volume, and flow rate of stormwater runoff can lead to destabilization of downstream channels and can also result in increased pollutant loading to waterways.

The Stormwater Management Program provides regulatory oversight and technical assistance to ensure proper design and construction of stormwater treatment and control practices as well as construction-related erosion prevention and sediment control practices, necessary to minimize the adverse impacts of stormwater runoff to surface waters throughout Vermont.

What's New with Vermont's Program

Vermont Construction General Permit (CGP) 3-9020 was amended and reissued on February 19, 2020, along with updates to the Low Risk Handbook for Erosion Prevention and Sediment Control and The Vermont Standards and Specifications for Erosion Prevention and Sediment Control. The new CGP will take effect 90 days from the date of issuance on May 19, 2020. Please see the Stormwater Program's [construction stormwater discharge permitting page](#) for information on the amended and reissued CGP.

The revised [Stormwater Rule](#) became effective on March 15, 2019. See the [Stormwater Permitting Rule Update](#) page for more information.

[FAQ for Title Attorneys](#)

Drainage

Adequate drainage is necessary for healthy turfgrass. Good surface drainage is the most reliable method for removal of water from course play areas. On gently sloped sites, surface drainage may be adequate to remove water without concern for erosion.

In general, putting surfaces should be tilted at no less than one-percent (1%) slope and fairways and roughs no less than two-percent (2%) to achieve adequate surface drainage.

Where the ground is very flat, subsurface drainage may be needed to assist in expedient removal. Where the ground is steep, subsurface drainage is helpful in reducing erosion by limiting the length and velocity of overland flow. Subsurface drainage is also installed to control a water table or to interrupt subsurface seepage or flow. Wherever possible, drainage should be directed into vegetative areas for biological filtration or into infiltration basins to help control the potential loss of nutrients and pesticides from the golf course.

Drainage is only as good as the system's integrity. Damaged, improperly installed, or poorly maintained drainage systems negatively impact play and increase risks to water quality. The drainage system should be routinely inspected to ensure proper function. Roots and animal activity can easily clog drains and prevent proper functioning.

Stormwater Capture

Capture systems should be considered part of the overall treatment of stormwater. Stormwater capture is desirable where the lowest quality of water is needed to conserve potable water, maintain hydrologic balance, and improve water treatment. This practice uses natural systems to cleanse and improve water treatment. Ponds often have the primary purpose of drainage and stormwater management and are also often a source of irrigation water. When the golf course is properly designed, rain and runoff captured in water hazards and stormwater ponds may provide most or all of the supplemental water necessary under normal conditions, though backup sources may be needed during times of drought.

Pond Location and Design

Designing a new pond requires considerations such as the size of the drainage area, water supply, soil types, and water depth. In addition to potentially serving as an irrigation water source, ponds support aquatic life. Therefore, the design of ponds should consider the needs of aquatic ecosystems, such as discouraging excessive growth of aquatic vegetation, supplying sufficient dissolved oxygen (DO) to support aquatic species, etc. Careful design may significantly reduce future operating expenses for pond and aquatic plant management. In addition, water resources should be managed to control or limit the spread of aquatic invasive species, such as submerged plants, fish or invertebrates.

Habitat Conservation

In addition to adhering to regulations that protect listed species, maintaining habitat to the extent possible during all phases of planning, design, and construction helps maintain biodiversity. Natural habitats provide food and shelter for numerous species,

including mammals, birds, fish, amphibians, reptiles, insects, and native plants. The "Pollinator" and "Sustainable Landscaping in Out-of-Play Areas" chapters of this document provide additional recommendations and BMPs for enhancing habitat on the golf course.

Best Management Practices for Design

- Involve a qualified golf course superintendent/project manager at the beginning of the design process to integrate sustainable maintenance practices in the development, maintenance, and operation of the course.
- Design the proposed changes to minimize or eliminate alteration of sensitive existing native landscapes. The plans should review alternate designs to determine the concept plan that best meets the objectives with the least disturbance.
- Design the changes to retain as many natural site characteristics as possible.
- Consider potential wear patterns in turf areas and create adequate space for ingress/egress at greens, tees, fairways and bunkers.
- Define play and non-play maintenance boundaries.
- Select a greens location that has adequate sunlight to meet plant specific needs and provides sufficient drainage, or design site improvements to reduce shade and improve drainage characteristics.
- Choose a green size and sufficient number of hole locations large enough to accommodate traffic and play damage, but not so large that it is not sustainable with your resources.
- Consider the placement of bunkers in relation to circulation patterns at greens so as not to concentrate turf wear.
- Consider the number, size and style of sand bunkers as they relate to resources available for daily maintenance.
- Be aware of bunker design as it relates to cost of construction and future maintenance. Make sure bunkers have suitable machine entry and exit points.
- Select the proper color, size, and shape of bunker sand that meets the course needs and sustainability.
- Ensure that wetlands have been properly delineated by a professional consultant before working in and around any wetlands.
- Ensure that proper permitting has been obtained before disturbing any tidal or non-tidal wetland or the regulated buffer zone.
- Establish and maintain an appropriately sized buffer around wetlands, springs, and spring runs.
- Install stream buffers to restore natural water flows and flooding controls.
- Install buffers in play areas to stabilize and restore natural areas that can attract wildlife species.
- Install detention basins to store water and reduce flooding at peak flows.
- Use a swale and berm system to allow for resident time (ponding) for water to infiltrate through the root zone to reduce lateral water movement to surface water bodies.

- When constructing drainage systems, pay close attention to engineering details such as subsoil preparation, the placement of gravel, slopes, and backfilling and placement of drainage gravel.
- Discharge subsurface drainage through pretreatment zones and/or vegetative buffers to help remove nutrients and sediments.
- The drainage system should be routinely inspected to ensure proper function.
- Install berms and swells to capture pollutants and sediments from runoff before it enters irrigation storage ponds.
- Monitor pond water level for water loss (seepage) to underground systems. If seepage is occurring, it may be necessary to line or seal irrigation ponds or install pumps to relocate water.
- Install water-intake systems that use horizontal wells placed in the subsoil below the storage basin. Use a post pump filter to remove particulate matter.
- Remove excess sediments in irrigation ponds to reduce irrigation system failures.
- Select an appropriate site for irrigation ponds to allow for adequate water levels to be maintained, including in times of drought.
- Design ponds so as to avoid peninsular projections and long, narrow fingers, which may prevent water mixing. Ponds that are too shallow may promote algal growth, excess sedimentation, and exhibit high temperatures and low DO levels.
- Reverse-grade around the perimeter of ponds to control surface water runoff and reduce nutrient loads.
- Construct random small dips and ridges (micro topography) on shorelines of a few inches to a foot to promote diversity for the aquatic plant community and provide a healthier and more productive littoral zone.
- Consult with a professional engineer when constructing a dam.
- Protect and enhance habitat by:
 - Identifying the different types of habitat specific to the site.
 - Identifying habitat requirements (food, water, cover, space) for wildlife species.
 - Identifying and preserving regional wildlife and migration corridors by avoiding or minimizing crossings. Design unavoidable crossings to accommodate wildlife movement.
 - Designing out-of-play areas to retain or restore existing native vegetation where possible.
 - Removing nuisance and exotic/invasive plants and replacing them with native species that are adapted to a particular site.
 - Maintaining clearance between the ground and the lowest portion of any fences or walls to allow wildlife to pass, except in areas where feral animals need to be excluded.
 - Retaining dead tree snags for nesting and feeding sites, provided they pose no danger to people or property.
- Constructing and placing birdhouses, bat houses, bee boxes, etc. in out-of-play areas.
- Design and locate cart paths to minimize environmental impacts. Construct the paths with permeable materials, if possible.

Construction

Documents

Prior to starting construction, construction plans that clearly communicate the scope of work are needed to communicate all aspects of the project to stakeholders to ensure that all parties understand the project. All critical data from the environmental resource inventory as well as key notes regarding construction processes should be included in the construction documents, as well as any conditions imposed in the permitting process. Documents should include sediment and erosion control or stormwater management plans that were established in the design phase.

Challenges often arise in construction that were not foreseen in planning and design. Development of clear and thoughtful plans and specifications can minimize costly changes during the work and will assist those involved in the project in responding to any unforeseen challenges. Proper planning can reduce the number of issues, but it is best if the responsible contractor has significant experience with golf course renovation or new construction. A well-qualified contractor will also be familiar with environmentally sound construction methods.

Construction Activities

Construction should begin with the project team meeting with the contractor(s) to review construction protocols. The purpose of this meeting is to define lines of communication, review the scope of work, review methods for reducing environmental impacts and for the contractor(s) to become familiar with permit requirements. Any natural resource areas impacted by the project should be clearly delineated prior to the meeting, field reviewed during the meeting, and permit requirements discussed that may impact construction activities. those areas.

The golf course architect, engineer, irrigation designer and other key consultants should remain involved through the construction phase to ensure plans and specifications are followed and permit conditions are met. The consultant's role in construction should be defined at the start of work.

During construction, the site should be kept as stable as possible to reduce erosion and stabilize sediments. For large renovation and new course projects, the contractor should attempt to limit the amount of disturbed area at one time, which may require completing and stabilizing a portion of the site prior to starting on a new area. On smaller projects, rather than phasing, the best method to prevent environmental impacts may be a narrow construction window. The construction schedule and work limitations should be tailored to each site and project. The emphasis during construction must be on performing the work with quality and care to minimize the potential for future problems.

Construction Techniques

Sound construction techniques include those processes and practices that control soil erosion and stormwater runoff. Examples of such techniques include the following:

- Installation of erosion control barriers prior to any land disturbance.
- Locating construction staging and fueling operations at least two-hundred feet (200') from any water body, wetland or sensitive area.
- Checking barriers prior to a predicted rainfall and removing excess siltation and repairing barriers immediately following a storm.
- Protection of drain inlets with gravel and silt fabric.

Figure 1-3. The drainage ditch was over-seeded with a erosion control mat, hay bales were placed inside the drainage ditch, and the entire project was surrounded by a silt fence prior to any construction taking place within the project.

Sediment Stabilization

The loss of topsoil from a site can be a problem for numerous reasons. Soil and sediment carried by wind and water transports contaminants with it. For example, erosion can enrich surface waters, where phosphorus, and to a lesser extent nitrogen, can cause eutrophication. When sediments and soils enter water, they can also increase turbidity, which can have harmful effects on aquatic plants and animals. Therefore, control measures need to be documented in an erosion and sediment control plan, put in place prior to any soil disturbance, and properly maintained. Wherever possible, a vegetative cover should be kept on the site until it is ready for construction. As soon as possible after construction activities are completed, the areas should be planted, sodded, or otherwise covered to prevent stabilize sediments and prevent erosion.

Construction Monitoring

The contractor, owner's representative or a hired consultant should be responsible for monitoring the construction process and providing any reports required by project permits. The level of diligence invested in monitoring can significantly influence the environmental and financial sustainability and viability of the project.

Best Management Practices for Construction

- Conduct a pre-construction conference with stakeholders.
- Use a qualified golf course contractor, such as a member of the Golf Course Builders Association of America, or one with significant local golf course construction experience.
- Consider limiting the area of disturbance at one time. Finish and stabilize one area before starting another area.
- Construction should be scheduled to maximize turfgrass establishment and site drainage.
- Monitor construction activities, maintain a construction progress report, and communicate the report to the proper permitting agencies.
- When constructing drainage systems, pay close attention to engineering details such as subsoil preparation, the placement of gravel, slopes, and backfilling to stabilize soils.
- Discharge subsurface drainage systems through pretreatment zones and/or vegetative buffers, where possible, to help remove sediments and nutrients.
- Utilize carbon filters at the end of drain pipes and cover drainage grates to avoid contamination.
- Develop and implement strategies to effectively control sediment, minimize the loss of topsoil, protect water resources, and reduce disruption to wildlife and plant communities.
- Integrate hydro-mulching, erosion blankets or straw mulch into the seeding process to enhance soil stabilization. Avoid using hay as mulch which may introduce unwanted weed seeds that may become a future problem.
- Check and repair erosion control barriers after every rain event.

External Programs

Golf courses can gain valuable recognition for their environmental education and certification efforts. Examples of external designations include Audubon International's [Cooperative Sanctuary Program for Golf](#) and the Groundwater Foundation's [Groundwater Guardian Green Site](#) program.

Water Quality Management and Protection

Preface

Protecting water quality involves recognizing the potential fate and transport mechanisms that can carry contaminants into water resources. If water quality contaminants reach surface or groundwater, the potential water quality impacts can include:

- Drinking water impairment if nitrogen as either nitrate (NO_3) or nitrite (NO_2) exceeds risk values that may adversely affect health.
- Nutrient enrichment of surface water.
- Sedimentation due to eroding soils.
- Toxicity to aquatic life.

Therefore, aligning water quality management efforts, such as stormwater management and lake and pond management with established, research-based BMPs protects water quality. A water quality monitoring program can be used to verify that water resources are being adequately protected. In addition, monitoring may demonstrate the presence of issues in water before enters a golf course such as upstream contamination.

Overall, protecting water quality includes not only implementing what is contained in this chapter, but what is discussed throughout this document, including:

- Design considerations such as the use of vegetated buffers.
- Fertilization strategies near surface waters.
- Pesticide usage.

A water quality monitoring program can be used to verify that water resources are being adequately protected. In addition, monitoring may demonstrate the presence of issues in water before enters a golf course such as upstream contamination.

Environmental Fate and Transport

Understanding contaminant fate and transport mechanisms will help superintendents protect water quality by minimizing the risk of off-movement of nutrients and pesticides applied to golf courses. Nonpoint sources pollution, which comes from many diffuse sources (as opposed to point source pollution that results from a single source), can occur due to the following fate and transport mechanisms of concern to golf course superintendents:

- Runoff, or the movement of water across the turf and soil surface, typically following a storm event or heavy irrigation. The potential for runoff is greatest on steep slopes.

- Leaching, or the downward movement of water through the soil and potentially into groundwater. Several variables influence the probability and rate of leaching, such as soil type and structure, vegetation, chemical properties, rate of precipitation, and depth to groundwater.
- Spray drift, or the movement of fine particles, or droplets, through the air while the pesticide is being applied. Droplet size and wind and weather conditions affect the potential for spray drift during pesticide applications.
- Vapor drift, or the movement of pesticide in the form of a gas or vapor during or after application. Pesticide formulation, wind, and atmospheric conditions affect the potential for vapor drift during pesticide applications.
- Volatilization, or the transformation of a pesticide from a solid or liquid to a gas or vapor after a pesticide application. Once airborne, volatile pesticides can come into contact with pesticide applicators or move long distances off-site.
- Spills, or unintended releases of chemicals, such as fertilizers, pesticides, hazardous materials, or petroleum products during transportation, storage, routine maintenance, and facility operations.

While most of the fate and transport mechanisms of concern can contribute to nonpoint sources of pollution, spills can be a point source of pollution. On golf courses, point sources of pollution can originate from:

- Storage and maintenance facilities.
- Unintended release of chemicals, such as pesticides, fertilizers, or fuel, during transportation, storage, or handling
- Drainage discharge outlets (e.g., the end of a drainage pipe).

Containment measures can easily prevent chemicals from becoming point sources of pollution during storage and handling. To prevent contamination of surface water, any accidental spills of chemicals must be diverted from surface water.

One additional potential contaminant is sediments, though primarily only a concern when bare soil is exposed, as during construction or renovation. Sedimentation is a concern when precipitation and irrigation carry soil particles (sediment) in runoff and deposit them into surface water. Too much sediment can cloud surface water, reducing the amount of sunlight that reaches aquatic plants and impairing aquatic species habitat. In addition, sediments can carry fertilizers, pesticides, and other chemicals attached to soil particles and transport them into waterbodies, causing algal blooms that lead to oxygen depletion. Sedimentation is handled through BMPs that control the volume and flow rate of runoff water, maintain adequate turf density, and reduce soil transport.

Pollution Prevention

Implementing BMPs can prevent or minimize the effects of a golf course on surface and groundwater, while ensuring and even enhancing public health and environmental quality. Pollution prevention is easier, less expensive, and more effective than

addressing problems after they happen. An integrated water quality protection system that incorporates the BMPs found throughout this document is based on a tiered concept as follows:

- Prevention – Stopping problems from occurring.
- Control – Having safeguards in place to handle any problems.
- Detection – Using a monitoring program to detect changes in environmental quality.

At any golf facility, preventive strategies should include combinations of land use controls and source prevention practices. Land use BMPs are engineered and incorporated into the course during golf course design and construction. They protect natural resources through primarily mechanical methods, such as retention basins, vegetated swales, and buffer areas around water courses.

Source prevention BMPs are implemented during golf course management operations to prevent sediment, nutrients, or pesticides from being introduced into ecologically sensitive areas. For example, pesticide management BMPs reduce the potential for drift and volatilization during pesticide applications. Irrigation BMPs prevent over-watering and are especially important for minimizing pollutant transport via runoff or leaching. Cultural practices BMPs maximize the water infiltration and water holding capacity of soils. Safeguards should be incorporated into the facility management to control any problems should they arise to prevent the contamination of water from spills. For example, many of the BMPs related to pesticide storage and handling as well as maintenance operations can prevent accidental releases of contaminants (pesticides, fertilizers, fuel, etc.) from becoming a point source of contamination.

Aligning golf course management practices with BMPs protects water quality on and downstream from the facility. While water quality monitoring on golf courses is typically voluntary, monitoring results demonstrate a commitment to water quality. Furthermore, providing monitoring information to local, regional, and state regulatory authorities and watershed groups can help foster positive relationships with these stakeholders.

Wetlands

Wetlands serve as filters for pollutant removal and as habitat for many species of birds, insects, fish, and other aquatic organisms. Vegetated buffers around the shore of a waterbody or another sensitive area slow, filter, and purify runoff before it can reach surface waters. Buffers may increase infiltration and ground water recharge. Existing wetlands on golf course properties should be maintained as a protected area and separated from managed turf areas with native vegetation or structural buffers. Constructed or disturbed wetlands may require a permit to be an integral part of the stormwater management system.

Best Management Practices for Wetlands

- Protect and maintain existing vegetation as natural buffers, to the maximum extent possible, during new course design and construction or during course renovation or general maintenance.
- Develop, enhance, restore, and protect wetland buffers. Manmade buffers should be designed to improve habitat diversity and include a mixture of fast and slow-growing native trees, shrubs, or grasses to provide a diverse habitat for wildlife.
- Encourage robust coastal and riparian vegetated buffers along the banks of golf course wetlands, perimeters of storage ponds and other waterbodies, and undeveloped uplands.
- Do not fertilize riparian buffer areas above the high-water mark. Leave them in a natural state.
- Reduce the frequency of mowing at a waterbody edge. Take clippings to upland areas.

Stormwater Management

Runoff, or the movement of water across the land surface from either precipitation or irrigation that does not infiltrate into the ground, is the conveying force behind nonpoint source pollution. Stormwater management refers to runoff from precipitation but applies to irrigation runoff as well. Stormwater management is the control and use of runoff and includes planning for runoff, maintaining stormwater systems, and regulating the collection, storage, and movement of stormwater.

BMPs reduce stormwater volume, peak flow, and nonpoint source pollution by promoting evapotranspiration, infiltration, detention, and filtering, as well as biological and chemical actions. BMPs help achieve such goals by:

- Keeping stormwater close to where it falls.
- Slowing down stormwater runoff.
- Allowing stormwater to infiltrate into the soil.

Stormwater management is best accomplished by a “treatment train” approach in which water is moved from one treatment to another by conveyances that themselves contribute to the treatment. These treatments include source controls, structural controls, and non-structural controls. An example of this treatment train approach is as follows: Stormwater is directed across vegetated filter strips, through a swale, into a retention pond, then out through another swale to a constructed wetland system.

Source Controls

The first car of the BMP treatment train are source controls to help prevent the generation of stormwater runoff or the introduction of pollutants into stormwater runoff. For example, during construction or redesign activities, strict adherence to erosion and sedimentation controls helps to prevent, or at least minimize, the possibility for sediment and nutrients to impact water quality through runoff. After construction, implementation

of BMPs can reduce the potential for off-site movement of contaminants such as nutrients and pesticides.

Structural Controls

Structural controls are often the next car in the treatment train and are design and engineering features on the course created to remove, filter, retain, or reroute potential contaminants (e.g., nutrients, pesticides, sediments) carried in surface runoff. They may also be combined to increase the treatment of stormwater. For example, sediment forebays can be used to pretreat stormwater before it is discharged to a dry extended detention basin, wet basin, constructed stormwater wetland, or infiltration basin. Periodic inspection and maintenance of all structural controls are essential to ensure they function as designed. Maintenance includes periodic cleaning of small basins, ponds, and forebays to remove sediments. The disruption and financial outlay of this effort is less than that for dredging an entire body of water.

In and around the clubhouse and other structures, opportunities should be identified to slow down the movement of water from impervious surfaces and allow for infiltration. For example, runoff from gutters and roof drains should flow into permeable areas. Rain gardens near these areas can be incorporated into the landscape design. Maximizing the use of pervious pavements, such as brick or concrete pavers separated by sand and planted with grass, allows stormwater to infiltrate into the soil as opposed to running off. Crushed stone and other permeable products are available for cart paths or parking lots.

Non-Structural Controls

Non-structural controls are the last car in the treatment train. Non-structural controls often mimic natural hydrology (e.g., constructed wetlands), hold stormwater, and filter stormwater via vegetative practices (e.g., filter strips and grassed swales). Turfgrass areas are extremely effective in reducing soil losses compared with other cropping systems, due to the architecture of the turf canopy, the fibrous turf root system, and the development of a vast macropore soil structural system that encourages infiltration rather than runoff. Additionally, turf density, leaf texture, rooting strength, and canopy height physically restrain soil erosion and sediment loss by dissipating impact energy from rain and irrigation water droplets.

Vermont Regulations

Vermont Stormwater regulations were briefly covered in the Planning, Design and Construction Planning Section, earlier in this paper. For more information about the Vermont Stormwater Regulations, [please click here](#).

Best Management Practices for Stormwater Management

- Design stormwater control structures to hold stormwater for appropriate residence times to help remove total suspended solids (TSS).
- Use a stormwater treatment train (in which water is conveyed from one treatment to another by conveyances that themselves contribute to the treatment).
- Use vegetated swales to slow and infiltrate water and trap pollutants in the soil, where they can be naturally broken down by soil organisms.
- Maximize the use of pervious pavements, such as brick or concrete pavers separated by sand and planted with grass. (Special high-permeability concrete and asphalt products are available for cart paths or parking lots.)
- Minimize directly connected impervious areas to the extent practical.
- Disconnect runoff from gutters and roof drains from impervious areas, so that it flows onto permeable areas that allow the water to infiltrate near the point of generation.
- Use depressed landscape islands in parking lots to catch, filter, and infiltrate water, instead of letting it run off. When hard rains occur, an elevated stormwater drain inlet allows the island to hold the treatment volume and settle out sediments, while allowing the overflow to drain.
- Ensure that no untreated discharges from pipes go directly to waterbodies.

Buffers

Buffers around the shore of surface waters, wetlands, or other sensitive areas filter runoff as it passes across. Buffers are the last line of defense to keep sediment out of streams and to filter out fertilizers and pesticides that might otherwise reach waterways.

Depending upon site-specific conditions, including the amount of available space and in-play versus out-of-play considerations, a range of buffer widths can be considered. Buffer widths as narrow as 10 feet have been shown to be effective. In most cases, a buffer of at least 100 feet is necessary to fully protect aquatic resources. Smaller buffers (toward the lower end of this range) still afford some level of protection to the surface waters and are preferable to no buffer at all. Protection of the biological components of wetlands and streams typically requires significantly greater buffer widths.

For vegetated buffer zones, ornamental grasses, wetland plants, or emergent vegetation around the perimeter and edges of surface waters serve as a buffer and wildlife habitat for many aquatic organisms and can be aesthetically pleasing. Use native plants for these plantings whenever possible. See the “Landscaping” chapter for more guidance on plant selection and the benefits of utilizing native plants. Riparian buffers along streams and rivers can be up to three different plant assemblages, progressing from sedges and rushes along the water’s edge to upland species.

Riparian buffers of sufficient width intercept sediment, nutrients, and pesticides in surface runoff and reduce nutrients and other contaminants in shallow subsurface water flow. Woody vegetation in buffers provides food and cover for wildlife, stabilizes stream banks, and slows out-of-bank flood flows.

Figure 2-1. The fairway edge was pushed left to accommodate the 25 foot buffer zone between the sprayed fairway and the creek. The rough is no longer sprayed.

Vermont Minimum Buffer Zones

- No pesticides are to be used within 100 feet of private drinking water supplies or public transient drinking water supplies.
- No pesticides are to be used within 200 feet of public, non-transient water supplies.
- No pesticides are to be used within 25 feet of any flowing surface waters or class II wetlands.
- No pesticides are to be used within 10 feet of impounded surface waters wholly on the golf course property.
- No pesticides are to be used within 25 feet of impounded surface waters not wholly on the golf course property.
- Additional buffer zones where no pesticides are to be applied shall be maintained as described in the management plan of your golf course.

Best Management Practices for Buffers

- Maintain healthy turf cover adjacent to surface waters to slow sediment accretion and reduce runoff flow rates.
- Vary the width, height, and type of vegetation to meet the specific functions of the buffer and growing conditions at the specific location.
- Encourage clumps of native emergent vegetation at shorelines.
- Plant shrubs and trees far enough from water edges so that leaves stay out of the water.

- Mow buffers on in-play areas in riparian areas to heights up to 4 inches.
- When mowing near buffer areas, return clippings away from the water or collect them (such as for composting in a designated area) so that runoff does not carry vegetation into the water.
- As a general practice, keep all chemical applications 10 to 15 feet away from the water's edge when using rotary spreaders and/or boom sprayer applications.
- When fertilizers or pesticides are needed in the buffer area, spot treat weeds or use drop spreaders or shielded rotary spreaders and boom sprayers to minimize the potential for direct deposit of chemicals into the water.

Lake and Pond Management

The management of lakes and ponds should include a clear statement of goals and priorities to guide the development of the BMPs necessary to meet those goals. Some of the particular issues superintendents should address to maintain the water quality of golf course lakes and ponds include:

- Pond design.
- Dissolved oxygen (DO) levels.
- Aquatic plant management.
- Near-shore management zones.

Pond Location and Design

Designing a new pond requires considerations such as the size of the drainage area, water supply, soil types, and water depth. In addition to potentially serving as an irrigation water source, ponds support aquatic life. The construction of ponds should consider the needs of aquatic ecosystems, such as discouraging excessive growth of aquatic vegetation and the DO needs for aquatic species. Careful design may significantly reduce future operating expenses for pond and aquatic plant management.

Dissolved Oxygen

Dissolved oxygen is the amount of oxygen present in water and is measured in milligrams per liter (mg/L). Adequate DO levels are required to sustain life in aquatic organisms and vary by species, the organism's life stage, and water temperature.

The amount of DO that water can hold depends on the physical conditions of the body of water (water temperature, rate of flow, oxygen mixing, etc.) and photosynthetic activity. Dissolved oxygen levels also differ by time of day and by season as water temperatures fluctuate, with warm water holding less DO than colder water. Similarly, a difference in DO levels may occur at different depths in deeper surface waters if the water stratifies into thermal layers. Fast-flowing streams hold more oxygen than impounded water. Lastly, photosynthetic activity also influences DO levels. As aquatic plants and algae photosynthesize during the day, they release oxygen. At night, photosynthesis slows down considerably or even stops, and algae and plants pull

oxygen from the water. In impoundments with excessive plant and algae growth, several cloudy days in a row can increase the potential for fish kills due to low DO during warm weather. Therefore, preventing excessive aquatic growth helps to maintain DO levels. The use of artificial aeration (diffusers) can also be used to maintain adequate DO, especially in small impoundments or ponds.

Aquatic Plants

Aquatic plants include algae and vascular plants. Phytoplankton, or algae, give water its green appearance and provide the base for the food chain in ponds. Tiny animals called zooplankton use phytoplankton as a food source. Large aquatic plants (aquatic macrophytes) can grow rooted to the bottom and supported by the water (submersed plants), rooted to the bottom or shoreline and extended above the water surface (emerged plants), rooted to the bottom with their leaves floating on the water surface (floating-leaved plants), or free-floating on the water surface (floating plants).

Aquatic plants are part of aquatic ecosystems. They provide a number of benefits, such as:

- Habitat for aquatic organisms (e.g., food and nesting sites).
- Oxygenation.
- Shoreline stabilization.
- Aesthetic appeal.

Aquatic plants growing on a littoral shelf may help protect receiving waters from the pollutants present in runoff. Ideally, littoral zones should have a slope of about 1 foot vertical to 6-10 foot horizontal to provide the best substrate for aquatic plant growth. In open areas, floating-leaved and floating plants suppress phytoplankton because they absorb nutrients from the pond water and create shade.

Particularly in shallow or nutrient-enriched ponds, aquatic plant growth can become excessive. Non-native plants can aggressively colonize aquatic environments. The excessive growth of any aquatic plant requires management. Following integrated pest management, a number of controls should be considered to deal with excessive aquatic plant growth, including:

- Prevention, such as reducing nutrient enrichment and avoiding the introduction of invasive species.
- Cultural practices, such as benthic barriers to prevent vascular plant growth.
- Mechanical removal.
- Chemical control.

Triploid grass carp are allowed in some states (typically with a permit) and are sometimes used as a biological control for aquatic plants.

Shoreline Management

Special management zones should be established around the edges of lakes and ponds. The management specifications should include a setback distance when applying fertilizers, as well as reduced mowing. Grass clippings should be collected near shorelines, as the phosphorus and nitrogen in clippings can impact water quality.

Waterfowl

The deposits of fecal matter by resident and migrating waterfowl (such as Canada geese) can substantially impact water quality through nutrient enrichment. On golf courses, shallow ponds with significant populations of waterfowl are most likely to be affected. In addition, large numbers of Canada geese can erode shorelines and thin the grass cover on greens and fairways, contributing to the potential for erosion. Efforts to control waterfowl have met with mixed success. Loud sounds, dogs, and hunting have been tried in order to deter them. However, many of these efforts do not lend themselves to golf courses, especially in more urban areas.

Best Management Practices for Lake and Pond Management

- Maintain water flow through lakes if they are interconnected.
- Establish wetlands where water enters lakes to slow water flow and trap sediments.
- Maintain appropriate erosion and sedimentation controls on projects upstream to prevent sedimentation and nutrient enrichment to waterbodies.
- Dredge or remove sediment before it becomes a problem.
- Establish DO thresholds to prevent fish kills, which occur at levels of 2-3 mg/L.
- Reduce stress on fish by keeping DO levels above 5 mg/L.
- Manipulate water levels to prevent low levels that result in warmer temperatures and lowered DO levels.
- Use artificial aeration (diffusers), if needed, to maintain adequate DO.
- Develop a comprehensive management plan that includes strategies to prevent and control the growth of nuisance aquatic vegetation.
- Keep phosphorus rich material (e.g., natural or synthetic fertilizers, organic tissues like grass clippings, or unprotected topsoil) from entering surface water.
- Install desirable native plants to naturally buffer DO loss and fluctuation.
- To control excessive aquatic plant growth, use an IPM approach that incorporates prevention, cultural practices, and mechanical removal methods in addition to chemical control.
- To reduce the risk of DO depletion, use an algaecide containing hydrogen peroxide instead of one with copper or endothall.
- Dredge or remove sediment as needed to improve aquatic habitat.
- Reverse-grade around the waterbody perimeters to control surface water runoff and to reduce nutrient loads.
- Discourage large numbers of waterfowl from colonizing golf course waterbodies.

- Use a multi-faceted, IPM approach to control nuisance animals, such as Canada geese.

Irrigation

Irrigation Scheduling

Proper irrigation can sustain plant energy reserves, increase root mass and depth, and reduce thatch accumulation. Irrigation should be applied as necessary to prevent wilt without oversaturating the soil/rootzone and without compromising playing conditions. In general, it is appropriate to water deeply and infrequently to promote root growth. In some cases, such as when watering-in products, it is important not to water past the rootzone to prevent leaching of products, including fungicides and wetting agents. It is also important to be mindful of how various areas of the course may require a different approach because of soil type (sand-based greens, etc.).

The goal of successful irrigation management is to limit excessive soil moisture while preventing wilt. Golf course managers strive to precisely apply water so PAW is only slightly greater than predicted ET. For many highly maintained turfgrass areas, like greens, small amounts of water are applied every night to replace what was lost the prior day. Soil moisture sensors can help further improve irrigation precision. These technologies can guide irrigation run times and identify locations that might benefit from additional hand watering.

During periods of sufficient natural precipitation, stress pre-conditioning through deficit irrigation can improve tolerance to future drought, heat, and cold stress. Deficit irrigation is the practice of limiting irrigation to slowly deplete soil PAW until the soil moisture approaches wilting points.

Computerized irrigation systems provide many advantages. Such systems can allow a superintendent to remotely cancel the program if the course has received adequate rainfall. Wi-Fi controllers connected to weather stations can adjust for changing ET. Clock-controlled irrigation systems preceded computer-controlled systems; many are still in use today and do not automatically adjust for changing ET rates. Therefore, frequent adjustment is necessary to compensate for the needs of individual turfgrass areas.

Maintained Turf Areas

The irrigation system should be designed and installed so that the putting surface, slopes, and surrounding areas can be watered independently. Precision irrigation scheduling of these areas is based on soil infiltration rates, soil water-holding capacity, plant water-use requirements, the depth of the rootzone, and desired level of turfgrass appearance and performance.

Non-Play and Landscape Areas

Courses should map any environmentally sensitive areas such as sinkholes, wetlands, or flood-prone areas, and should identify any listed species or habitats of concern.

Natural vegetation should be retained and enhanced for non-play areas to conserve water. The most efficient and effective watering method for non-turf landscape is micro-irrigation. Older golf courses may have more irrigated and maintained acres than are necessary. With the help of a golf course architect, golf course superintendent and other key personnel, the amount of functional turfgrass can be evaluated and transitioned into non-play areas. For more information on non-play area landscaping, see the “Sustainable Landscaping in Out-of-Play Areas” and “Pollinator” chapters of this document.

Best Management Practices for Irrigation Scheduling

- The irrigation system should be designed and installed so that the putting surface, slopes and surrounding areas can be watered independently.
- Install part-circle heads to conserve water and reduce unnecessary stress to greens and surrounds.
- Avoid use of a global setting. Make adjustments to watering times per head based on turf species and soil and slope characteristics
- Base water times on actual site conditions for each head and zone.
- Adjust irrigation run times based on current local meteorological data.
- Use computed daily ET rate to adjust run times and manually adjust automated ET data to reflect wet and dry areas on the course.
- Install rain switches to shut down the irrigation system if enough rain falls in a zone.
- Use soil moisture sensors to bypass preset irrigation schedules or to create on-demand schedules.
- Permanent irrigation sprinklers and other distribution devices should be spaced according to the manufacturer's recommendations.
- Spacing should be based on average wind conditions during irrigation.
- Reducing dry spots and soil compaction improves water infiltration, which in turn reduces water use and runoff in other areas.
- When possible, irrigation should occur in the early morning hours before air temperatures rise and relative humidity drops.
- Base plant water needs on ET rates, recent rainfall, recent temperature extremes, and soil moisture.
- Use mowing, verticutting, aeration, wetting agents, nutrition, and other cultural practices to maximize infiltration and minimize water loss as runoff.
- Visually monitor for localized dry conditions or hot spots to identify poor irrigation efficiency or a failed system device.
- Install inground (wireless) soil moisture sensors in the rootzone and use in conjunction with handheld moisture meters for each irrigation zone to enhance scheduled, timer-based run times.
- Wireless soil moisture systems should also be installed to prevent damage from aeration.

- Designate 50% to 70% of the non-play area to remain in natural cover according to "right-plant, right-place" principle of plant selection that favors limited supplemental irrigation and on-site practices.
- Incorporate natural vegetation in non-play areas.
- Use micro-irrigation and low-pressure emitters in non-play areas to supplement irrigation.
- Routinely inspect non-play irrigation systems for problems related to emitter clogging, filter defects, and overall system functionality.

Water Conservation and Efficient Use Planning

Potable water supplies in many areas of the United States are limited, and demand continues to grow. The challenge is to find solutions to maintain the quality of golf while using less water. Opportunities to conserve water exist when courses are initially designed and during renovation, during irrigation system design and use, and by incorporating the use of management zones. For example, some new courses are designed using a "target golf" concept that minimizes the acreage of irrigated turfgrass and improves the use of the water applied. Similarly, hand-watering specific areas of stress-prone turfgrass can result in significant water savings. If properly designed, water hazards and stormwater ponds can capture rain and runoff that may provide supplemental water under normal conditions, though backup sources may be needed during severe drought.

Water Budgets

The development of a water budget establishes a benchmark for golf course water requirements that can be compared with actual water use, ultimately confirming whether water is being used efficiently or whether changes in management strategy are needed. Using a water budget to accurately estimate a course's water requirements can translate into improved playing conditions for golfers, lower operating and maintenance costs, and improved resource management. Water budgets take into account the size of the property, historic climate data, effective rainfall, and plant factors. This helps managers make informed decisions about their current water use and the effectiveness of programs designed to reduce water use. The water-budget approach is recognized by the United States Environmental Protection Agency (USEPA) and other federal and state agencies as a science-based approach for estimating landscape water requirements. The United States Golf Association (USGA) provides an online [Water Budget Calculator](#) along with [step-by-step instructions](#) for assistance in creating a facility-specific water budget. Precision water management is one of the most important practices for maintaining high-quality golf turf while conserving water resources, as discussed in detail later in this chapter.

Precision water management can be achieved through efficient irrigation practices that replace only the amount of irrigation water needed to maintain healthy turf in playing areas. It requires an efficient and properly functioning irrigation system and regular cultural practices that increase the water-holding capacity of soil.

Turfgrass Selection

Turfgrass selection is an important component of a water conservation efforts. The increased availability of improved turfgrass species and varieties provide an excellent opportunity to select the most well adapted turf to specific site conditions. If selected for drought tolerance, some turfgrass varieties require less water to survive and maintain playability. The [National Turfgrass Evaluation Program](#) (NTEP) provides information on top performing cultivars for various desirable turfgrass traits, including tolerance to drought, traffic and diseases.

Out-of-Play Areas

In addition to utilizing well-adapted cultivars for in-play areas, existing golf courses can convert out-of-play area turfgrass to native plants, grasses, or ground covers to reduce water use and augment the site's aesthetic appeal. Native plant species also provide wildlife with habitat and food sources, such as native flower areas that benefit pollinators. After establishment, site-appropriate plants normally require little to no irrigation. [The Native Plant Trust](#) (formerly New England Wild Flower Society) provides information on native plants in the region, and additional lists for drought-resistant landscapes can be found through state university extension programs, including the [University of Massachusetts](#) and [University of New Hampshire](#). See also the "Pollinators" and "Sustainable Landscaping in Out-of-Play Areas" chapters for more information on native and drought-tolerant plants.

Wetting Agents

Wetting agents can be useful for managing a number of water-related issues, such as improving irrigation efficiency, assisting in the retention of water in the soil profile, aiding in infiltration, preventing and treating localized dry spot (LDS), or serving as a spray adjuvant when applying pesticides or plant growth regulators (PGRs).

Research shows preventative applications can increase soil water uniformity and sustain high visual turfgrass quality at very low levels of irrigation (30% potential evapotranspiration) [Kostka et al., 2005]. Preventative applications of wetting agents can also increase irrigation precision, which reduces water use while maximizing playing conditions. Late fall applications may reduce water repellency in soils well into the spring, reducing the potential for LDS in the spring.

Wetting agents are especially useful in restoring the wettability of hydrophobic (water repellent) sand-based soils. Turfgrass grown on sand-based root zones can develop severe localized dry spots especially when the stand is irrigated deep and infrequently (wet and dry cycles). Wetting agents help promote water infiltration and retention in these hydrophobic areas by reducing the surface tension of water and restoring the polar attraction of water to soils.

In addition to a variety of chemistries available for wetting agent products, natural options to improve water movement in the soil include yucca extracts and gypsum (calcium sulfate).

Figure 3-1. The browned turf was sodded after the fairway wetting agent application and showed signs of drought stress, while the remainder of the fairway looks lush.

Drought Planning and Response

Besides operating the facility in a manner that promotes water conservation, superintendents should identify water-conserving measures in time of severe shortages before water usage restrictions are enacted at a state or local level. Water conservation plans should identify opportunities to achieve a 10%, 30%, and 50% reduction in water use. The USGA publication [*BMPs and Water-Use Efficiency/Conservation Plan For Golf Courses: Template and Guidelines*](#) can facilitate the creation of the plan. In addition, superintendents should monitor drought status when needed. Drought conditions for each state can be accessed through the National Integrated Drought Information System on the [U.S. Drought Portal](#).

Communication should be maintained with water managers, golf club members, and the public to explain these water conservation efforts as a proactive approach to addressing water-related issues.

Best Management Practices for Water Conservation and Efficient Use Planning

- Develop a water budget for the course.
- Select drought-tolerant varieties of turfgrass to minimize water use.
- Utilize hand watering or targeted irrigation to conserve water.
- Control invasive plants or plants that use excessive water.
- Reduce the amount of area on the golf course that is irrigated, if possible, such as non-play areas.
- Utilize wetting agents to increase soil water uniformity, minimize localized dry spot, and sustain high visual turfgrass quality at very low levels of irrigation.
- Water-in wetting agents sufficiently.

- Identify opportunities to achieve water use reductions before mandatory water restrictions are enacted in times of drought.
- Develop a drought plan for the property based on the USGA Drought Plan Template that includes all aspects of facility management.
- During a drought, monitor the state's drought status to ensure compliance with restrictions.

Preface

The judicious use of supplemental water keeps turfgrass and landscape plants healthy, while providing the firm, fast playing surfaces that golfers desire. BMPs that conserve and protect these water resources are integral to facility management. Conservation and efficiency-related efforts consider the strategic use of course and irrigation design, computerized and data-integrated scheduling, and alternative water supply options that support plant health and reduce the potential for negative impacts on natural resources.

Irrigation BMPs may also provide an economic, regulatory compliance, and environmental stewardship advantage to courses that integrate them into an irrigation management plan. BMPs are not intended to increase labor or create undue burden. If applied appropriately, irrigation-related BMPs can help stabilize labor costs, extend equipment life, reduce repairs, and limit overall personal and public liability while protecting and conserving natural resources. Additional comprehensive information that includes detailed irrigation-related BMPs can be found in [Best Management Practices for Golf Course Water Use](#) (Connecticut DEP, 2006).

Irrigation Management Decision-Making

An irrigation system should be operated based only on the moisture needs of the turfgrass -- or to water-in a fertilizer or chemical application as directed by the label. Irrigation scheduling must take plant water requirements and soil intake capacity into account to prevent excessive water use that could contribute to leaching and runoff. Plant water needs are determined by several factors including evapotranspiration (ET) demands, recent rainfall, recent temperature extremes, and soil moisture. ET rates and soil moisture replacement should serve as primary factors to help determine the irrigation schedule rather than a calendar-based schedule.

Evapotranspiration

Evapotranspiration describes the water lost through soil evaporation and plant transpiration and is influenced by the climatic conditions such as solar radiation, temperature, and relative humidity. Evaporative demands (and ET) increases with increasing solar radiation, high temperatures, and decreasing relative humidity. The irrigation of turf based on ET replacement is effective in preventing leaching losses and therefore eliminating potential sources of waste, which is an important water conservation strategy. The scheduling of irrigation using ET replacement also helps to quantify water in terms of the "amount" in inches to be applied to turf. Deficit irrigation is

another way ET can be used to avoid overwatering and even reduce water consumption. In this approach, turf is irrigated with only a portion of the calculated ET (e.g., 60 to 80% ET) for a period of days until wilt becomes too difficult to manage, or a rain event occurs. In either case, soil water levels are restored to facilitate turf recovery either through irrigation or natural precipitation. In the latter case, a water savings is accomplished by applying less water daily, allowing for natural rainfall to provide necessary water for turf maintenance. Accuracy of ET calculations, and therefore their potential to reduce water consumption, can be enhanced through the use of crop coefficients (Kc) that account for variations in water use among different plant species. Research conducted at the University of Massachusetts determined Kc values for creeping bentgrass, Kentucky bluegrass, and perennial ryegrass at fairway and rough mowing heights. Detailed information on how to correctly use [ET-based irrigation scheduling](#) for cool-season grasses can be found as part of the Turf Irrigation Series, University of Massachusetts.

It is important to note that because electric/mechanical clocks cannot automatically adjust for changing ET rates, frequent adjustment is necessary to compensate for the needs of individual turfgrass areas using these older systems.

Soil Infiltration Rate and Plant Available Water

The rate of infiltration depends on soil texture. Sandy soils, with their higher porosity, have greater infiltration rates than silty or clay soils. Plant available water (PAW) represents the amount of water (expressed in inches) available per inch of soil depth that a plant can access for transpiration. A soil moisture probe indicates the total volumetric water content, which is greater than the PAW for a soil. The PAW can be estimated with a soil moisture meter by subtracting the current soil moisture content from the moisture content when the turfgrass wilts. Plant available soil moisture and infiltration rates are provided in Table 3-1.

Table 3-1. Available soil moisture and infiltration rates for common soil textures.

Soil Texture	Soil Type	Typical plant-available moisture per foot of soil depth (inches)	Infiltration rate (inches h ⁻¹)
Light, sandy	Coarse sand Fine sand	0.25 – 0.75 0.75 – 1.00	Fast (0.5 – 6+)
Medium, loamy	Loamy sand Sandy loam Fine sandy loam Silt loam	1.10 – 1.20 1.25 – 1.40 1.50 – 2.00 2.00 – 2.50	Moderate (0.25 – 0.5)
Heavy, clay	Silty clay loam Silty clay Clay	1.80 – 2.00 1.50 – 1.70 1.20 – 1.50	Slow (0.1 – 0.25)

Rootzone Depth

The depth of effective turfgrass rooting should be determined with a soil probe or spade. Golf greens and tees have the majority of roots in the top several inches of soil, while fairways and roughs will typically have deeper roots. Exact root depths depend on grass species and time of year. The soil infiltration rate and root zone depth should be used together to estimate the amount of water that needs to be available to the root system to avoid wilting. The rooting depth is multiplied by the PAW to estimate the total amount of water available to the turfgrass.

Soil Moisture

To accurately measure local precipitation, the proper use of rain gauges, rain shut-off devices, soil moisture sensors (especially sensors utilizing time domain reflectometry [TDR] technology), and other irrigation management devices should be incorporated into the site's irrigation schedule. Monitoring of soil moisture, in addition to calculating ET rates and visual observations of turfgrass, assists in meeting turfgrass water needs while conserving water resources.

Irrigation Water Suitability

Irrigation water quality must be suitable for plant growth and pose no threat to public health. Because water quality can influence soil quality and turfgrass performance, it is advisable to test irrigation water periodically for factors that can compromise the turf/soil system. This is especially true for non-potable water irrigation sources, such as retention ponds and recycled water. Excess nutrients and/or salts may accumulate to levels that are toxic to plants -- potentially influencing aquatic plant growth in rivers, lakes, and estuaries -- and that contribute to a variety of soil-related problems. For example, irrigation water high in sodium and low in calcium and magnesium applied frequently to clay soils can break down soil structure, cause precipitation of organic matter, and reduce permeability.

Routine analysis should provide the following information: conductivity, pH, Na, Ca, Mg, K, CO_3^{2-} , HCO_3^- , SO_4^{2-} , Cl^- , P, B, nitrate-N, hardness, and sodium adsorption ratio (Landschoot, 2016). The results can be used to address possible issues with soil salinity and plant health caused by poor water quality.

When necessary, water system treatment options should be included in the operating budget to address water quality and equipment maintenance.

Best Management Practices for Water Suitability

- Account for the nutrients in effluent (reuse/reclaimed) water when making fertilizer calculations.

- Test reclaimed water regularly for dissolved salt content.
- Routinely monitor the shallow groundwater table of fresh water for saltwater intrusion or contamination by heavy metals and nutrients.
- Flush with fresh water or use amending materials regularly to move salts out of the root zone and/or pump brackish water to keep salts moving out of the root zone.
- Amend sodic water systems appropriately (with gypsum or an appropriate ion) to minimize sodium buildup in soil.
- Monitor sodium and bicarbonate buildup in the soil using salinity sensors or routine soil tests.

Irrigation Water Sources

Golf course designers and managers should endeavor to manage water resources to minimize impacts on freshwater drinking supplies, while also promoting plant health and protecting the environment. Studies of water supplies are recommended for irrigation systems, as are studies of waterbodies or flows on, near, and under the property. Water sources for irrigation must be dependable and offer sufficient resources to accommodate turf grow-in needs and ongoing maintenance. [Environmental Best Management Practices for Virginia's Golf Courses](#) describes the methodology and provides example calculations to determine water requirements using a seasonal and maximum bulk water requirement analysis (see pages 37 and 38).

The opportunity to identify and use alternative water supply sources may also be appropriate, depending on the availability of infrastructure and additional management costs associated with non-potable water.

When using groundwater, the area around the wellhead should be protected, and safe land-use practices should be instituted to protect aquifers from accidental contamination. This includes protecting wellheads from physical impacts, keeping them secure, and sampling wells according to the monitoring schedule required by the regulating authority. Before installing new wells, the local regulatory authorities should be contacted to determine the permitting and construction requirements and the isolation distances required from potential sources of contamination. New wells should be located up-gradient as far as possible from potential pollutant sources, such as petroleum storage tanks, septic tanks, chemical mixing areas, or fertilizer storage facilities.

VERMONT GROUNDWATER PROTECTION, MANAGEMENT AND COORDINATION

Groundwater Protection, Management and Coordination

The Vermont legislature created Chapter 48 to set up a comprehensive groundwater management program and put groundwater in trust for the

public now and for future generations. The three main components are:
Information or the science and mapping of groundwater resources including the location and movement of groundwater, its use, contamination, remediation and protection.

Regulation: classifying types of groundwater, developing and implementing rules that govern or permit activities that may impact groundwater.

Communication or outreach to provide help and guidance to towns, municipalities and the public through partnerships with EPA, USGS, VGS, VRWA and other groups to encourage and support protecting groundwater resources.

The Vermont Groundwater Management Plan lays out three high level objectives:

- A) improve information available for GW management decisions,
- B) protect public health and safety and the environment, and
- C) expand communications.

Each of these objectives has specific tasks that are tracked and modified as needed over a 5-year running cycle as part of an implementation plan. The members of the Groundwater Coordinating Committee provide invaluable assistance in developing and revising this management plan.

Groundwater Protection Rule & Strategy

The Groundwater Protection Rule and Strategy was revised and adopted on July 6, 2019. The purpose of this Rule and Strategy is to establish:

classes of groundwater;

a process for groundwater reclassification;

a set of standards for groundwater quality protection; and

incorporate a process into DEC regulatory programs to ensure that activities that present a potential threat to groundwater are designed, managed, and permitted to protect groundwater resources

Vermont's Current Rule

Chapter 12 - Groundwater Protection Rule and Strategy - effective July 6, 2019

Best Management Practices for Irrigation Water Sources

- Identify appropriate water supply sources that meet seasonal and bulk water allocations for grow-in and routine maintenance needs.
- When developing new water sources, incorporate surface storage (lined ponds) with wellhead withdrawals to conserve water by conservation of rainfall, site drainage, and runoff as a supplemental water source.
- Use alternative water supplies/sources that are appropriate and sufficiently available to supplement water needs and follow guidelines for use.
- Ensure that reclaimed, effluent, and other non-potable water supply mains have a thorough cross-connection and backflow prevention device in place and are operating correctly. Adhere to cross-connection regulations.
- Post signs in accordance with local utility and state requirements when reclaimed water is in use.
- Surround new wells with bollards or a physical barrier to prevent impacts to the wellhead.
- Maintain records of new well construction and modifications to existing wells.
- Obtain a copy of the well log for each well to determine the local geology and well depth. These factors will have a bearing on how vulnerable the well is to contamination. Sample wells for contaminants according to the schedule and protocol required by various state agencies.
- Inspect wellheads and the well casing at least annually for leaks or cracks. Make repairs as needed.
- Use backflow-prevention devices at the wellhead, on hoses, and at the pesticide mix/load station to prevent contamination of the water source. Adhere to various state cross-connection regulations.
- Properly plug abandoned or flowing wells.
- Never apply a fertilizer or pesticide next to or near a wellhead.
- Never mix and load pesticide next to or near a wellhead if not on a pesticide mix/load pad.

Irrigation System Design

Site Assessment

An assessment of the facility should be conducted prior to developing an irrigation system design. The assessment should include site-specific features, such as water sources, soil types (see the [Web Soil Survey](#)), soil physical properties, microclimates,

slopes, sun, wind, and shade exposures, and a seasonal and bulk water requirement analysis.

The site assessment should also evaluate the impact of design elements, such as design features and concepts, planned or existing turfgrass varieties, and planned or existing drainage systems. The system design should include a general irrigation schedule with recommendations and instructions on modifying the schedule to meet these site-specific needs.

Design Considerations

A well-designed irrigation system should operate at peak efficiency and be designed and installed to optimize water use efficiency, focusing on water placement and distribution. The design should maximize water use, reduce operational cost, conserve supply, and protect water resources. Detailed BMPs for irrigation system design are published by the Irrigation Association in [2014 Landscape Irrigation Best Management Practices](#).

The irrigation system design should meet the site-specific needs identified by the water quantity analyses and the site assessment. The system's capacity to deliver water should not exceed the infiltration of the soils on site, as that will lead to runoff. Though the design of an irrigation system is complex, some of the most important design decisions that influence the efficiency and effectiveness of water usage include those related to sprinkler and piping placement, sprinkler coverage and spacing, and communication options.

Sprinklers

Multi-row sprinkler systems provide the most efficient use of water and can respond to specific moisture requirements of selected areas. Newer designs with multiple nozzle configurations provide increased flexibility and improved distribution uniformity. Single row systems do not uniformly distribute water and increase the risk of runoff. Double-row systems offer improved efficiency over single-row coverage, although manual watering or other types of supplemental watering may be needed outside the fairway area and into the extended rough. Sprinkler layouts can be specific to each area. For example, part-circle sprinklers can be arranged to avoid overspray of impervious surfaces and to apply water only to the green surface or in heavy traffic areas. Manual quick-coupler valves can be an important conservation element and should be installed near greens, tees, and bunkers so these can be hand-watered during severe droughts. Irrigation systems strive to provide uniform water distribution and to achieve distribution uniformity (DU) values near 80%. After installation, nozzles and irrigation head runtimes should be optimized to maintain uniform soil moisture distribution. That can be easily monitored with a soil moisture probe.

Communication

For precise irrigation control, advanced irrigation control systems that schedule each green, tee, and fairway separately allow course managers to adjust for differences in microclimates and root zones. Weather stations that calculate and automatically program water replacement schedules also provide opportunities for more precise irrigation, as do soil moisture sensors placed in multiple locations. Additional features may include internet connectivity to allow for remote adjustment or cancellation of schedules as well as rain stop safety switches that either shut down the system in the event of rain or adjust schedules based on the amount of precipitation.

Best Management Practices for Irrigation System Design

- Seek assistance from irrigation professionals, such as from Certified Golf Course Irrigation System designers and [WaterSense-certified](#) irrigation consultants.
- New and upgraded irrigation system designs should deliver water with maximum efficiency, focusing on precision water placement and distribution.
- Design and/or maintain a system to meet a site's peak water requirements under normal conditions with the flexibility to adapt to extreme conditions or local restrictions.
- Design should account for optimal distribution efficiency and effective root-zone moisture coverage. Target 80% or better DU.
- Design should allow the putting surface, slopes, and surrounds to be watered independently.
- The design package should include a general irrigation schedule with recommendations and instructions on modifying the schedule for local climatic, soil, and growing conditions. It should include the base ET rate for the particular location.
- The application rate must not exceed the infiltration rate, which is the ability of the soil to absorb and retain the water applied during any one application. Conduct saturated hydraulic conductivity tests periodically.
- The design operating pressure must not be greater than the available source pressure.
- The design operating pressure must account for peak-use times and supply-line pressures at final buildout for the entire system.
- Turf and landscape areas should be zoned separately. Specific-use areas that should be zoned include greens, tees, primary roughs, secondary roughs, fairways, trees, shrubs and flower beds.
- Design should account for the need to leach out salt buildup from poor-quality water sources by providing access to fresh water.
- Permanent irrigation sprinklers and other distribution devices should be spaced according to the manufacturer's recommendations.
- Spacing should be based on average wind conditions during irrigation.
- Distribution devices and pipe sizes should be designed for optimal uniform coverage and flow rate.

- Distribution equipment, such as sprinklers, rotors, and micro-irrigation devices, in a given zone must have the same precipitation rate.
- Heads for turf areas should be spaced for head-to-head coverage.
- Water supply systems (for example, wells and pipelines) should be designed for varying control devices, rain shut-off devices, and backflow prevention.
- Water conveyance systems should be designed with thrust blocks and air-release valves.
- Flow velocity must be 5 feet per second or less.
- Pipelines should be designed to provide the system with the appropriate flow and pressure required for maximum irrigation uniformity.
- Pressure-regulating or compensating equipment must be used where the system pressure exceeds the manufacturer's recommendations.
- Equipment with check valves must be used in low areas to prevent low head drainage.
- Isolation valves should be installed in a manner that allows critical areas to remain functional.
- Manual quick-coupler valves should be installed near greens, tees, and bunkers and in fairways if possible, so that these areas can be hand-watered during severe droughts.
- Use part-circle or adjustable heads to avoid overspray of impervious areas, such as roadways and sidewalks, and surface waters such as lakes, ponds, and wetland margins.
- Update block type sprinkler valves with single head control to conserve water and to enhance efficiency.
- Incorporate multiple nozzle configurations to add flexibility and enhance efficiency and distribution.
- Ensure heads are set level to the ground.
- Provide backup option(s) for loss of power/pumps with PTO, gas/diesel, potable pump or generator to provide irrigation to greens and tees at a minimum.

Pump Station

Pump stations should be efficient and sized to provide adequate flow and pressure. They should be equipped with control systems that protect distribution piping, provide for emergency shutdown necessitated by line breaks, and allow maximum system scheduling flexibility.

Where feasible, variable frequency drive (VFD) pumps and/or pump station should be used. These systems only expend enough energy to meet the demands of the irrigation pump(s). VFD systems reduce water hammer to fitting, pipe, and sprinklers when systems are pressurized.

Best Management Practices for Pump Stations

- The design operating pressure must account for peak-use times and supply-line pressures at final buildout for the entire system.
- Maintain the air-relief and vacuum-breaker valves by using hydraulic pressure-sustaining values.
- Install VFD systems to lengthen the life of older pipes and fittings until the golf course can afford a new irrigation system.
- An irrigation system should also have high- and low-pressure sensors that shut down the system in case of breaks and malfunctions.
- Pumps should be sized to provide adequate flow and pressure.
- Pumps should be equipped with control systems to protect distribution piping.

Irrigation System Installation

To ensure maximum efficiency, the irrigation system must be installed per the design and specifications. The installer must ensure that there is qualified supervision of the installation process and that a qualified irrigation specialist inspects and approves the system installation.

Best Management Practices for Irrigation System Installation

- The designer must approve any design changes before construction.
- Construction and materials must meet existing standards and criteria.
- Prior to construction, all underground cables, pipes, and other obstacles must be identified and their locations flagged. ([Dig Safe 811](#)).

Figure 3-2. Installation of a well designed system.

Irrigation System Maintenance and Performance

Calibration and Auditing

Irrigation system maintenance on a golf course involves four major efforts: calibration and auditing, preventive maintenance, corrective maintenance, and record keeping. Personnel charged with maintaining a golf course irrigation system face numerous challenges. This is particularly true for courses with older or outdated equipment. Irrigation audits can be conducted to assess the system function, ensuring that the irrigation system works reliably and is cost effective. The Irrigation Association has published [irrigation audit guidelines](#).

Maintenance

Good system management starts with good preventive maintenance procedures and record keeping. Corrective maintenance is simply the act of fixing what is broken and may be as simple as cleaning a clogged orifice or as complex as a complete renovation of the irrigation system. As maintenance costs increase, an evaluation of whether a system renovation is needed should be conducted.

Winterization

Winterizing protects irrigation system pipes from damage due to water expanding and rupturing the pipe walls and fittings. Golf courses need to drain or use compressed air to remove water from lateral and mainlines pipes before temperatures drop below freezing, as well as from all sprinkler heads and quick couplers. Many facilities operate an independent irrigation system below the frost line, allowing the facility to apply water during cold periods to dormant turfgrass in an effort to prevent winter desiccation and winter kill.

Spring Start-up

Spring start-up of the irrigation system is essentially the reverse of the steps taken to winterize the system. At the time of start-up, the system should be inspected for corrective maintenance issues.

Best Management Practices for Irrigation System Maintenance – Calibration and Auditing

- Examine turf quality and plant health for indications of irrigation malfunction or the need for scheduling adjustments.
- Evaluate pressure and flow to determine that the correct nozzles are being used and that the heads are performing according to the manufacturer's specifications.
- Visually inspect the entire system to identify necessary repairs or corrective actions and make repairs before carrying out other levels of evaluation.

- Conduct an annual irrigation audit to facilitate a high-quality maintenance and scheduling program for the irrigation system.
- Conduct an annual pump test and inspections.
- Submit required withdrawal reports to the appropriate regulatory agency.

Best Management Practices for Irrigation System Maintenance – Preventive Maintenance

- Inspect the system daily for proper operation by checking computer logs and visually inspecting the pump station, remote controllers, and irrigation heads. A visual inspection should be carried out for leaks, misaligned or inoperable heads, and chronic wet or dry spots so that adjustments can be made.
- Observe the system in operation regularly to detect controller or communication failures, stuck or misaligned heads, and clogged or broken nozzles.
- Check filter operations frequently. Keeping filters operating properly prolongs the life of an existing system and reduces pumping costs.
- Monitor the power consumption of pump stations for problems with the pump motors, control valves, or distribution system.
- Increase frequency of routine inspection/calibration of soil moisture sensors that may be operating in high-salinity soils.
- Inspect irrigation pipes and look for fitting breaks caused by surges in the system.
- Install thrust blocks to support conveyances.
- Maintain air-relief and vacuum-breaker valves.
- Have qualified pump personnel perform regular checks of amperage to accurately identify increased power usage that indicates potential problems.
- Check application/distribution efficiencies annually.

Best Management Practices for Irrigation System Maintenance – Winterization

- Flush and drain above-ground irrigation system components.
- Remove water from all conveyances and supply and distribution devices that may freeze. Use compressed air or open the drain valves at the lowest point on the system.
- Change filters, screens, and housing; remove drain plugs and ensure any water is removed from the system. Secure systems and close and lock covers/compartment doors to protect the system from vandalism and from animals seeking refuge.
- Drain any above-ground pump casings that may have “trapped” water.
- Record metering data before closing the system.
- Secure or lock any remote irrigation components, including satellites.
- Perform pump and engine servicing/repair before winterizing.

Best Management Practices for Irrigation System Maintenance – Spring Start Up

- Power up the pump station and pump motors before prior to using the system. By completing this task ahead of recharging the system, the coils inside the motors heat up and remove any moisture that collected during the offseason.
- Keep the water pressure at 60 PSI or lower when priming the lines.
- Operate each of the sprinklers until all excess air is flushed from the irrigation system.
- Check the functionality of air pressure relief valves.
- Inspect the entire system for any corrective maintenance issues.

Metering

Rainfall may vary from location to location on a course; the proper use of rain gauges, rain shut-off devices, flow meters, soil moisture sensors, and/or other irrigation management devices should be incorporated into the site's irrigation schedule. It is also important to measure the amount of water that is actually delivered through the irrigation system, via a water meter or a calibrated flow-measurement device. Knowing the flow or volume will help determine how well the irrigation system and irrigation schedule are working.

Best Management Practices for Metering

- Calibrate equipment periodically to compensate for wear in pumps, nozzles, and metering systems.
- Properly calibrated flow meters, soil moisture sensors, rain shut-off devices, and/or other automated methods should be used to manage irrigation.
- Flow meters should have a run of pipe that is straight enough – both downstream and upstream – to prevent turbulence and bad readings according to manufacturer's requirements.
- Flow meters can be used to determine how much water is applied.

Irrigation Leak Detection

Irrigation systems are complex systems that should be closely monitored to ensure leaks are quickly detected and corrected. An irrigation system should also have high- and low-pressure sensors that shut down the system in case of breaks and malfunctions. Golf courses without hydraulic pressure-sustaining valves are much more prone to irrigation pipe and fitting breaks because of surges in the system, creating more downtime for older systems.

Best Management Practices for Irrigation Leak Detection

- Monitor water meters or other measuring devices for unusually high or low readings to detect possible leaks or other problems in the system. Make any needed repairs.
- Monitor the system daily for malfunctions and breaks. Log water usage daily.

- Ensure that control systems provide for emergency shutdowns caused by line breaks and allow maximum system scheduling flexibility.

Irrigation System Renovation

Renovating a golf course irrigation system can improve system efficiencies, conserve water, improve playability, and lower operating costs.

Best Management Practices for Irrigation System Renovation

- Determine the age of the system to establish a starting point for renovation.
- Identify problems and their costs to determine which renovations are appropriate.
- Identify system performance improvements that maximize the efficient use of the current system.
- Evaluate the cost of renovation and its return on financial and management benefits.

Irrigation Record Keeping

Careful record keeping is an important part of managing an irrigation system, as well as part of regulatory requirements for reporting water withdrawal.

Vermont Groundwater Withdrawal Reporting and Permitting

Existing or new groundwater withdrawals of greater than 20,000 gallons per day need to be reported annually for the water usage during the preceding calendar (i.e., on or before September 1, 2010, the water usage for 2009 needs to be reported). A Groundwater Withdrawal Reporting Form (see below) needs to be submitted for each individual groundwater source each reporting year. [Click here for more information.](#)

[Daily Groundwater Withdrawal Reporting Form](#)

[Monthly Groundwater Withdrawal Reporting Form](#)

Best Management Practices for Record Keeping

- Keep records of filter changes, as this could be an early sign of system corrosion, well problems, or declining irrigation water quality.
- Document equipment run-time hours. Ensure that all lubrication, overhauls, and other preventive maintenance are completed according to the manufacturer's schedule.
- Monitor and record the amount of water being applied, including system usage and rainfall and identify areas where minor adjustments can improve performance.

- Document and periodically review the condition of infrastructure, such as pipes, wires, and fittings. If the system requires frequent repairs, it is necessary to determine why these failures are occurring.
- Document all corrective actions.
- Adhere to all regulatory reporting requirements for water withdrawal.

Water Quality Monitoring

Preface

Monitoring can be used to set a pre-construction baseline for water quality. Routine monitoring can be used to measure water quality improvements and identify any areas where corrective actions should be taken. Monitoring can also demonstrate the presence of issues in water as it enters a golf course property not related to any impacts from facility management.

Golf course superintendents wanting to develop and implement a water quality monitoring program should first review available baseline water quality data, which can include both groundwater and surface water monitoring. Baseline data can be assessed to determine the likely origin of contaminants, measure the extent of sedimentation and nutrient inputs, and estimate the potential impacts to surface water and groundwater. In addition to monitoring surface and/or groundwater, water quality monitoring of irrigation sources (particularly water supply wells and storage lakes) provides valuable agronomic information that can inform nutrient and liming programs.

Water Quality Analysis

Testing protocols can be simplified to test only those parameters that are directly influenced by course management, including organic and inorganic levels of nitrogen and phosphorus and a pesticide screen for selected pesticides used on the course. Additional analytes can include watershed basin-specific parameters of concern, such as sediments, suspended solids, and heavy metals. During measurements of dissolved oxygen, pH and alkalinity can also be sampled.

Samples should be analyzed by a certified laboratory, and all quality assurance/quality control (QA/QC) procedures must be followed. The purpose of QA/QC is to ensure that chemical, physical, biological, microbiological, and toxicological data are appropriate and reliable. If a golf course should ever need to produce data for an agency or go to court to defend the facility, the data must meet QA/QC standards to be defensible as evidence.

Interpreting Water Quality Results

Water quality can be analyzed by private companies or by university laboratories. Interpretation and use of water quality monitoring data depends to a large extent on the goal of the monitoring program. For example, the results may be analyzed to compare:

- Values over time.
- Values following implementation of BMPs, such as IPM measures.
- Monitoring points entering the site and leaving the site.

Results should also be interpreted and compared with the state's water quality standards, if standards have been established for the parameter being evaluated. Data analysis can also be used to identify issues that may need corrective action, based on findings such as a spike in nutrient levels. For example, operator error in nutrient applications, an extreme weather event, or some combination of factors may be responsible. Water quality problems can often be addressed by simple changes to a course's existing nutrient management program.

Best Management Practices for Water Quality Monitoring

- Review existing sources of groundwater and surface water quality information.
- Develop a water quality monitoring program.
- Establish baseline quality levels for water.
- Identify appropriate sampling locations and sample at the same locations in the future.
- Visually monitor/assess any specific changes of surface waterbodies.
- Follow recommended sample collection and analytical procedures.
- Conduct seasonal water quality sampling. The recommendation is four times per year.
- Partner with other groups or volunteer water quality monitoring programs if possible, to share data and monitoring costs.
- Compare water quality monitoring results to benchmark quality standards.
- Use corrective measures when necessary.

Groundwater Monitoring

Groundwater monitoring from wells located at the hydrologic entrance and exit from the course may be the best way to evaluate a golf course's impact on water quality. If groundwater monitoring data from these locations is not available from existing sources, monitoring wells can be installed by private companies. Installing groundwater monitoring wells can be relatively expensive, but the expense may be justified in certain cases where the origin of contamination can only be determined through comparison of water quality entering and exiting the property. To identify the appropriate site for monitoring wells, groundwater flow information is required. If this information is not available, experienced environmental engineering firms or the United States Geological Survey (USGS) can assist in determining suitable monitoring well locations.

Surface Water Monitoring

For new golf courses or renovation projects in the planning stage, baseline water quality levels should be measured prior to construction at points of entry and exit of flowing water sources on or surrounding the golf course and on any surface water. This information can be used to form a baseline of flow and nutrient/chemical levels. For established courses, ongoing, routine water sampling provides meaningful trends over time. Post-construction surface-water quality sampling should begin with the installation

and maintenance of golf course turf and landscaping and should continue through the first three years of operation and during the wet and dry seasons every third year thereafter, provided that all required water quality monitoring has been completed and the development continues to implement all current management plans. A single sample is rarely meaningful in isolation. It may also be wise to sample if a significant change has been made in course operation or design that could affect nearby water quality.

Water Quality Sampling

The number of monitoring samples is highly variable and depends on the size, location, and number of water sources on or near the golf course. The entry and exit points of golf course water sources are logical sampling points. However, sampling and analysis of standing water sources (i.e. ponds), springs, and any other irrigation sources should also be included. It may also be wise to sample if a significant change has been made in course operation or design that could affect nearby water quality.

Developing a water quality monitoring program on golf courses is often limited to surface water monitoring and sometimes groundwater monitoring. Stream biomonitoring is a method to evaluate the condition of a stream or river using biological surveys of the living organisms that inhabit the waters. It is a way of inferring the water quality based on what organisms are present. Sampling of stream macrobenthic invertebrates (macrobenthic invertebrates are relatively large organisms that inhabit bottom substrates of streams and lakes for at least part of their life cycles) is a useful addition to a monitoring program, as the composition and diversity of these species can be used as a relative assessment tool for stream health. Such sampling can often be undertaken by university students in fulfillment of course work.

Golf Turf Fertilization and Nutrient Management

Preface

Fertilization is the key cultural practice that supplies essential nutrients to turfgrass plants. A sound fertilization program ensures turfgrass persistence, performance, and quality. Under many instances, turfgrasses require supplemental fertilizers to provide nutrients not supplied in adequate amounts by the soil.

Proper fertilization, combined with appropriate mowing, irrigation, and pest control, produces healthy and attractive turf that withstands the wear and tear of intended use. Proper fertilization of turfgrass is extremely important because of the high demands for turfgrass performance and quality, the wide use and establishment of turfgrasses under less than favorable conditions, and the great demands placed on turfgrass for high recuperative capacity and wear tolerance. This requires a high level of cultural expertise including knowledge of plant nutrition, soils, and fertilizer technology and application. Variables to consider when developing a fertilizer program include turfgrass species, mowing height and frequency, soil type and structure, irrigation, intended use of the turfgrass, temperature, environmental factors such as shade or sun, and whether clippings are returned.

Essential Elements for Turfgrass and Plant-Available Ionic Forms

At least 17 elements are considered essential for turfgrass growth. Macronutrients, the nutrients required in relatively large amounts, include carbon (C), hydrogen (H), oxygen (O), nitrogen (N), phosphorus (P), potassium (K), calcium (Ca), magnesium (Mg), and sulfur (S). Micronutrients, nutrients required in relatively smaller amounts, include iron (Fe), manganese (Mn), zinc (Zn), boron (B), molybdenum (Mo), copper (Cu), chlorine (Cl), and nickel (Ni). Turfgrasses obtain C, H, and O from the atmosphere and water; the remainder are obtained primarily by roots from the soil. (Under certain special conditions, foliar uptake of nutrients happens through directed foliar nutrient sprays.) For turfgrasses to take up an essential element from the soil solution, it must be present in a plant-available ionic form, and water must be moving into the plant from the soil. The plant-available ionic forms vary with each element (Table 5-1).

Table 5-1. Essential elements and their plant-available forms.

Macronutrients		Micronutrients	
Element	Plant-available ion	Element	Plant-available ion
Nitrogen (N)	NH_4^+ , NO_3^-	Iron (Fe)	Fe^{2+} , Fe^{3+}
Phosphorus (P)	H_2PO_4^- , HPO_4^{2-}	Manganese (Mn)	Mn^{2+}
Potassium (K)	K^+	Boron (B)	H_2BO_3^-
Sulfur (S)	SO_4^{2-}	Copper (Cu)	Cu^{2+}
Calcium (Ca)	Ca^{2+}	Zinc (Zn)	Zn^{2+}

Magnesium (Mg)	Mg ²⁺	Molybdenum (Mo)	MoO ₄ ²⁻
		Chlorine (Cl)	Cl ⁻
		Nickel (Ni)	Ni ²⁺

Though present in large quantities in most soils, the availability of macronutrients in the soil may be low if they are not in the plant-available forms. When availability is below optimum, N, P, and K are most often supplied by applying fertilizers. Calcium and Mg are routinely supplied from liming materials. Sulfur fertilization of turfgrasses is generally not needed in New England because S requirements are met through atmospheric deposition of S-containing air pollutants and S mineralized from organic matter. Sulfur is also a component of some N- and P-containing fertilizers and certain pesticides.

Micronutrients are rarely deficient in New England soils, and therefore applying them on a routine basis is generally not necessary. However, on sand-based rootzones, micronutrient applications are warranted based on soil test results and can improve turfgrass performance. A commonly applied micronutrient on both soil and sand rootzones is Fe. This is not necessarily based on a deficiency of Fe, but because application of Fe, particularly as a foliar spray, has been shown to increase the dark green color in cool-season turfgrasses resulting in higher turf color quality.

Soil pH affects nutrient availability to plants (Figure 5-1). Maintaining soil pH to slightly less than neutral (e.g., 6.8), results in optimal availability of all the nutrients. Acidic (<6.0) or alkaline (>7.0) soils may result in deficiencies of both macro- and micronutrients due to pH-dependent changes in ionic forms or complexing with other elements that precipitate in the soil solution, thus becoming unavailable.

Figure 5-1. Relationship of soil pH and nutrient availability.

<https://www.turfcaresupply.com/resources-and-services/soil-ph-nutrient-chart>

Basis for Fertilization

Fertilization of turfgrasses should be based on site-specific nutrient inputs and outputs and the needs of a particular turfgrass species. Nutrient inputs include fertilizers, organic matter decomposition, residue additions (i.e., return of clippings), atmospheric deposition, and nutrients contained in the irrigation water (Petrovic, 1990). Outputs of nutrients from a turf system include the removal of clippings, gaseous losses (denitrification and volatilization), losses with percolating water (leaching) and runoff, and immobilization in the soil organic matter or mineral fractions (Petrovic, 1990). When turfgrass nutrient requirements exceed the supplying capacity of the system, fertilization is needed to make up for this deficiency.

The capacity of any particular turfgrass plant to obtain available nutrients from the soil influences the fertilization requirements. Factors to consider include:

- Root extent and depth. Roots can only absorb nutrients where they are growing. Therefore, conditions that favor deep and extensive root development improve nutrient uptake capabilities. Compacted and/or wet soils have restricted rooting depths that may prevent adequate nutrient uptake.
- Thatch layer. If a large quantity of roots are located in the thatch layer, nutrients in the underlying soil may not be utilized and soil tests may incorrectly report the nutrient availability in the soil profile where roots should be concentrated. Furthermore, a thick thatch layer may restrict fertilizer movement so that nutrients may not reach the roots in the soil in sufficient amounts to support demand.
- Organic matter decomposition. The amount and rates of mineralization of organic matter affect the nutrient availability and existing fertility of a soil. Soils with high organic matter content may not need as frequent fertilizer applications as soils with low organic matter content if they are decomposing at a reasonable rate and releasing available forms of essential elements.
- Soil pH. The solubility of all essential elements and soil microbial activity is affected by pH. Maintaining a soil pH between 6 and 7 for turfgrasses is typically recommended, although turfgrasses can grow reasonably well over a wide range of pH values.
- Cation Exchange Capacity (CEC). Finer textured soils have a higher CEC and a higher nutrient-supplying capacity than coarse textured soils and sand rootzones. Therefore, more frequent fertilizer applications may be required on coarse-textured soils and constructed sand rootzones than on fine-textured soils to supply necessary nutrition and minimize nutrient leaching.
- Losses. Gaseous losses via denitrification and volatilization and nutrient losses via leaching and runoff decrease the amount of nutrients available for turf growth. Applying fertilizers at appropriate times and rates and avoiding overwatering of turf limit these losses.

Determining the Need for Specific Nutrients

Soil test results should be the foundation of a turfgrass fertilization program. Soil tests are used routinely to determine the availability of essential nutrients. Past fertilization practices and responses are useful guides for N fertilization. Tissue tests are becoming more widely utilized but are expensive compared with soil tests. Reflectance meters and digital image analysis may prove to be useful in a turfgrass N management program in the near future (Karcher and Richardson, 2013; Bell et al., 2013; Guillard et al., 2016; Inguagiato and Guillard, 2016).

Other conditions and factors affect the needs for specific nutrients. The inherent nutrient supplying capacity of the soil and organic matter mineralization potentials may decrease or increase the need for specific nutrients based on turfgrass performance and quality goals. Incidence and severity of diseases, insects, and other pest problems may demand changes in current fertilization practices, as may abiotic environmental stresses such as drought, heat, or cold conditions. Increased traffic directly and indirectly affects nutrient needs and uptake. Clipping management (returned vs. removed) greatly affects the availability and nutrient status of a turfgrass soil. When clippings are returned to the

turf, fertilization rates may be decreased by as much as 50% without loss in quality (Kopp and Guillard, 2002). Contrary to popular belief, grass clippings decompose rapidly under normal mowing practices and do not contribute to thatch (Kopp and Guillard, 2004). Therefore, whenever possible, clippings should be returned as part of a sustainable nutrient management program.

Common sense should provide a guiding influence on nutrient management programs for turf. When the potential for water quality impacts exist, turfgrass fertilizer applications need to be closely managed. For example, fertilization (especially excess nutrient application) near open waterbodies or on sites with high leaching potential may contribute to contamination of receiving waters. In these cases, the solubility and release rates of N formulations, timing of application, and application rate need to be carefully considered.

Importance of Specific Nutrients to Turfgrass Growth and Development

Although all essential elements are required for adequate turfgrass growth and development, some elements are more frequently associated with specific growth responses in turf (Table 5-2).

Table 5-2. Selected nutrients and general effects ('+' positive and '-' negative) on turfgrass growth and quality.

Turfgrass Growth Response	N	P	K
Rooting	+/-	+	
Shoot Growth (leaves, tillers, rhizomes, stolons)	+

Composition of turf community	+/-	+/-	

Vermont Nutrient Management Plan

Nutrient Management Plan (NMP) Information

For a list of all requirements, [click here](#).

[Nutrient Management Plan \(NMP\) Help](#) – The NMP part of the regulations, with tips on how to write that section following each. Also use the fertilizer recommendations for golf turf below to help in writing your nutrient management plan narrative.

[Fertilization and Nutrient Management Guidelines for Golf Turf in Vermont](#)

Dr. Sid Bosworth, Extension Professor, University of Vermont: Sid.Bosworth@uvm.edu

UVM's Agricultural and Environmental Testing Lab Website (A great place to get your soil tested): http://pss.uvm.edu/ag_testing/

You are not required to use UVM, but this lab will test soil and provide fertility recommendations for golf course turf in VT. Forms can be downloaded from this site. Codes to indicate 'golf course turf' can be found on the back of the order form.

[Nitrate Leaching Index Information Sheet](#) - how to find yours in 12 easy steps!

Natural Resources Atlas Website: <https://anrmaps.vermont.gov/websites/anra5/>

Forms

These are not required, but using them and completing them properly will ensure that you are following the pesticide and fertilizer record keeping requirements under the new regulations. Remember these records need to be maintained for 5 years. Updated December 2017.

Use one or the other for pesticide records:

[VT GC Daily PESTICIDE Records \(pdf\)](#) – for printing and keeping paper records

[VT GC Daily PESTICIDE Records \(xls\)](#) – excel spreadsheet to download for keeping electronic records.

Use one or the other for fertilizer records:

[VT GC Daily FERTILIZER Records \(pdf\)](#) – for printing and keeping paper records

[VT GC Daily FERTILIZER Records \(xls\)](#) – excel spreadsheet to download for keeping electronic records.

Soil Testing

Soil testing plays an important role in a turfgrass nutrient management program. Soil tests measure the soil pH (how acidic or alkaline the soil), amounts of available macro- and micronutrients, and other chemical or physical properties such as soil texture, bulk density, porosity, CEC, soluble salts, and organic matter. A turf manager needs to know about the various soil properties to apply the proper amount of fertilizer and lime. Too little fertilizer and lime may result in reduced turf quality, vigor, stand persistence, performance, and tolerance to biotic and abiotic stresses. Too much fertilizer may increase problems with diseases and insects, reduce environmental stress tolerances, deplete plant storage carbohydrates (i.e., food energy), increase the potential for nutrient losses off-site, and increase economic losses due to unneeded nutrients.

Soil tests for the plant available N forms of NH_4^+ and NO_3^- are available, but their utility for turf is limited because the rapid transformations that can occur for these various forms of N in the turf-soil system make the tests largely meaningless, unless they are conducted at two-week or shorter intervals during the growing season (Geng et al., 2014). This is logistically challenging on most golf courses. Consequently, N fertilization needs for turf have been based historically on various measures of turfgrass species growth and quality such as clipping yields, color, visual symptoms of N deficiency, shoot density, tillering, density, rooting characteristics, and recuperative capacity. New soil tests for labile (i.e., “active”) N and C that predict mineralization have shown promise for guiding N fertilization of cool-season turfgrasses (Moore et al., 2019a and 2019b).

All **Vermont golf courses** are required to take a soil sample, every three years, for all areas that received fertilizer applications. The soil must be analyzed for available phosphorus using the **Modified Morgan Extract**. [Click here, for more information about the Nutrient Management Program, including specific details about the program.](#)

Soil Sampling Procedure

The first step in a nutrient management program is to collect soil samples. Soil samples can be collected any time the ground is not frozen or excessively wet (which makes it too hard to get a representative sample), and not shortly after a lime or fertilizer application. Because temperature affects the mineralization and weathering of organic matter and parental minerals, it is best to take soil samples the same time each year so that seasonal differences do not confound the test results. When renovating or establishing turfgrass, soil samples should be taken two or more weeks prior to beginning work in the area.

Soil test recommendations are only as good as the procedures used to collect samples. Generally, many samples are taken from one uniform area, mixed thoroughly in a clean pail, and a subsample taken from the many mixed samples to represent the area. A “Z” or “W” sampling pattern can be used to collect the samples in an area, with the samples taken along the path of the pattern. As a general guideline, 10 to 15 samples should be taken across the specific sections (separate greens, tees, fairways, and roughs into

separate sections). Areas that are fertilized, mowed, irrigated, managed differently, or are unusual should be sampled separately to avoid biasing the sample.

Soil samples should be collected to a depth of no more than 4 inches for established turfgrass and 6 inches where a new seedbed has been prepared. When limited thatch is present in the profile, it should not be included in the sample. On sites where the majority (e.g., $\geq 75\%$) of roots are restricted to the thatch/mat layer, it may be preferable to include this portion in the sample.

Remember that the decision to retain or discard thatch influences soil test results from year to year. Once collected, the subsample should be placed into a plastic bag and labeled with the corresponding collection area. Avoid heating the sample once placed in the plastic bag (e.g., a car trunk on a hot day can become very warm) because some chemical changes may occur and erroneous conclusions may be reached regarding the need for fertilizers.

Soil Testing Frequency

Newly established turf areas *should* be tested annually for a few years until the nutrient status of the soil becomes stable. For established turf without problems, a soil sample every two to three years *should* be adequate. Problem turf areas *should* be sampled annually until problems are corrected. High-value turf areas probably *should* be sampled annually because the margin for error in these systems is so low.

In Vermont, any area that receives fertilizer applications *is required* to be tested, at least, once every three years. The soil sample *must* be kept on file for 5 years.

Soil samples can be analyzed by commercial laboratories, land-grant university systems, or agricultural experiment stations such as:

- Connecticut – [University of Connecticut Soil Nutrient Analysis Laboratory](#) and the [Connecticut Agricultural Experiment Station](#).
- Maine – [University of Maine Agricultural and Forest Experiment Station's Analytical Laboratory and Maine Soil Testing Service](#).
- Massachusetts – [University of Massachusetts Soil & Plant Nutrient Testing Laboratory](#).
- New Hampshire – [University of New Hampshire Cooperative Extension Soil Testing Services](#).
- Rhode Island (soil pH only) – [University of Rhode Island Master Gardener's Program](#).
- Vermont – [University of Vermont Agricultural and Environmental Testing Lab](#).

Expression of Soil Test Results

The ways in which soil test results are expressed varies among soil testing laboratories. Some lab results are expressed on a qualitative basis: low, medium (or adequate), high;

or below optimum, optimum, and above optimum. Other labs express results on a quantitative basis: pounds of available nutrient per acre or in units of parts per million (ppm). Soil tests in the United States are traditionally based on the “acre furrow slice,” which is the volume of soil in the upper 6 to 7 inches of the soil profile. Historically, this relates to the standard depth of a plow, and on average this amount of soil is considered to weigh 2 million lbs. per acre. Using this as a base, it can be reasoned that if a nutrient was reported to be available at 2 lbs. per acre, then 2 lbs. of nutrient are available per 2 million lbs. of soil, or in its simplest form: 1 ppm. Therefore, pounds per acre are two times the ppm. It may be important when interpreting soil tests to understand whether the values are reported in pounds per acre or ppm. Soil test results also differ on how results are interpreted and how recommendations are formed.

Sufficiency Level of Available Nutrients (SLAN)

The Sufficiency Level of Available Nutrients (SLAN) (Eckert, 1987) soil test interpretation and recommendation method is used by most university and governmental soil testing laboratories in the United States. This method relies on data collected under field conditions where response curves are generated for as many turf species and soil types as possible. The underlying principle of the method is that a beneficial turf response to added fertilizer is observed when the soil extractable-nutrient levels are below optimum, and the response to fertilization becomes increasingly small as the soil extractable-nutrient levels approach an optimum (Figure 5-2). There is a low probability of response to fertilizer additions when extractable-nutrient levels are at optimum or beyond; often the response will plateau.

Figure 5-2. Theoretical turfgrass growth or quality response in relation to plant-available essential elements in the soil, according to the SLAN philosophy of nutrient management.

Categories and ranges for extractable nutrients used by the New England land-grant university soil testing laboratories for their SLAN turfgrass fertilizer recommendations are provided in Tables 5-3 to 5-7.

Table 5-3. University of Connecticut Soil Nutrient Analysis Laboratory categories and ranges for modified Morgan extractable nutrients, lbs/ac (or ppm) (Pettinelli, personal commun.).

	Below optimum	Optimum	Above optimum
Ca	0 – 1,799 (0 – 899.5)	1,800 – 2,399 (900 – 1,199.5)	>2,400 (>1,200)
Mg	0 – 174 (0 – 87)	175 – 249 (87.5 – 124.5)	>250 (>125)
P	0 – 5 (0 – 2.5)	6 – 20 (3 – 10)	>21 (>10.5)

Base Cation Saturation Ratio (BCSR)

Soil test interpretation and recommendations may also be established on the base saturation percentage of the CEC. This method of testing is known as the Base Cation Saturation Ratio (BCSR) method (Bear et al, 1945) and is based on the concept that an ideal ratio of cations on the CEC sites produces the best plant response. Most private soil testing laboratories in United States use this method. According to this method, the proper ratio of nutrients in the soil exists when the percentage base saturation is approximately in the ranges shown in Table 5-8.

Table 5-8. Proposed optimum percentage base saturation for the BCSR method for soil test interpretation and recommendations (Albrecht, 1975) and University of Maine Agricultural and Forest Experiment Station's Analytical Laboratory and Maine Soil Testing Service optimum ranges or value for modified Morgan extractable nutrients, % saturation (Hoskins, 1997).

	Proposed Optimum Base Saturation Ranges

Interpretation of the BCSR often depends heavily on specific ratios – Ca:Mg 6.5:1, Ca:K 13:1, and Mg:K 2:1. When the ratios vary from the proper ratio, fertilizer applications are recommended to restore the balance. Many turfgrass and soil scientists do not accept the BCSR method because no substantial scientific evidence exists to support the claim that maintaining an ideal ratio of soil cations maximizes crop response (Kopittke and Menzies, 2007; Chaganti and Culman, 2017). Under the BCSR method, it is possible that additional fertilizer is recommended even when the extractable-nutrient levels are high to very high. Regardless, turf practitioners indicate successful results following the BCSR method (see Simmons’ response in Schlosseberg and Simmons, 2012). In calcareous sand-based rootzones, the BCSR method could result in misleading ratios and cation saturation percentages (St. John and Christians, 2010) and should not be used as the sole factor in developing a turfgrass fertility program for sand-based rootzones that have either a low CEC or are calcareous (St. John and Christians, 2013).

Minimum Level for Sustainable Nutrition (MLSN)

The Minimum Level for Sustainable Nutrition (MLSN) is a newer soil test interpretation and fertilizer recommendation approach that identifies the minimum concentration of a soil element that supports “good” turf growth while maintaining desired turf quality and playability levels (Stowell and Woods, 2013). In the approach, nutrients are extracted from soils of “well performing turf” and concentrations are fit to a log-logistic model that identifies the concentration where 10% of the soil samples fall below that point in the distribution. This concentration is then defined as the MLSN. (Woods et al., 2016). Figure 5-3 shows the relationship for P.

MLSN phosphorus data

Figure 5-3. The cumulative distribution function for phosphorus to identify the MLSN guideline.

At the 0.1 probability level, 10% of the samples report phosphorus values lower than 18 ppm (red line). This is the phosphorus MLSN guideline. The blue line indicates the conventional guideline of 50 ppm for phosphorus. Fifty-nine percent (probability = 0.59 = sustainability index) of the samples report values lower than the conventional phosphorus guideline (Woods et al., 2014).

From the graph, one can plot out manually or use the predictive equation to estimate the MLSN at a Probability = 0.10 (i.e., concentration of the lowest 10% of well-performing samples). This is in contrast to the other methods that attempt to place soil test values into specific categories (e.g., optimum, low, high, etc.). The thinking in the MLSN method is that if the turf is performing well with soil nutrient concentrations below the optimum levels defined by the traditional SLAN and BCSR methods, then why add extra fertilizer? Development of the MLSN approach with more than 17,000 soil samples (and continuing) indicates that good quality turf can be maintained at concentrations well below that indicated as optimum with the SLAN or BCSR methods. Using the Mehlich III extractant, the MLSN guideline levels are 37, 21, 348, 47, and 7 mg kg⁻¹ for

K, P, Ca, Mg, and S, respectively. These are much lower than optimum as indicated by the SLAN method (see Tables 5-4 to 5-7 above), and fertilizer additions would be recommended if following the SLAN interpretation. Since the MLSN levels are much lower than the conventional optimum levels, less fertilizer is recommended. This can result in substantial savings on most golf courses.

To date, the MLSN levels are based on the Mehlich III extractant. As indicated in the next section, most of New England soils are extracted with the Morgan or modified Morgan extractant. Therefore, unless soil test data comes from a lab utilizing the Mehlich III extractant, the MLSN values will not be directly translatable to soil test results based on other extractants.

Extractants

Various extractants are used in soil testing laboratories. Often, the use of a particular extractant is regionally related or dependent on soil type or properties. In New England, soils are generally acidic, low in organic matter, high in Al and Fe, and have a relatively high sand content. For these soils, the Morgan (contains sodium acetate) or modified Morgan (contains ammonium acetate) extractants are regularly used for soil tests at the soil testing laboratories of the University of Connecticut, Connecticut Agricultural Experiment Station, University of Maine, University of Massachusetts, and University of Vermont. The Morgan extractants are weak acids and are appropriate for most types of soils in New England. Recently, the Mehlich III extractant (containing acetic and nitric acids along with ammonium fluoride, ammonium nitrate, and EDTA), which is the typical extractant for mid-Atlantic states, is being used to test soil samples submitted to the University of New Hampshire's soil testing services. The University of Rhode Island does not offer a soil testing service (other than pH through the Master Gardener's program). Some commercial soil testing services in New England will send the soil samples to analytical labs in the Midwest, where the Bray extractant (containing hydrochloric acid and ammonium fluoride) is used for soil testing.

It is important to understand the relationship between the various soil testing extractants and why they produce their results. For example, if the Bray, Mehlich, and Morgan extractants are used on subsamples of the same soil from New England, the results for nutrient availability may not agree. Usually the Bray and Mehlich will remove similar amounts of Ca, Mg, and K as the Morgan extractants, but more P is extracted because the Bray (hydrochloric acid) and Mehlich (nitric acid) are much stronger-acid extractants than the Morgan's (acetic acid); they may remove up to 10 times more P from the soil. Good calibration data may not be available with the Bray and Mehlich III methods for extractable P for New England soils. Therefore, P results should not be compared from different extractants. It is best to use the same extractant to monitor short- and long-term changes in soil test values over time.

Best Management Practices for Soil Testing

- Divide the course into logical sampling components such as greens, fairways, tees, roughs, etc., for each hole.
- Take 10 to 15 soil samples randomly from each respective section of the golf course and blend them together to provide a representative, uniform soil sample (separately for greens, tees, fairways, and roughs).
- Take each soil sample at the same depth.
- Use an extractant appropriate for the course's soils (historically, the Morgan and modified-Morgan extractants are best for New England soils).
- Ensure that the same extractant is used for each test in order to compare soil test results over time.
- Keep soil tests from prior years and review to observe changes over time. This practice can provide good evidence of the impact of the nutrient management plan.

Plant Tissue Analysis

Turfgrass fertilization recommendations can also be based on tissue testing. With tissue testing, the clippings are analyzed for nutrient concentration and this value is compared to a critical range indicating deficiency, sufficiency or excess (Table 5-9). Some believe that this method is more accurate than a soil test because it measures the concentrations of nutrients actually taken up by the grass rather than estimated from extractable soil values.

Table 5-9. Suggested sufficiency ranges for tissue nutrient concentrations of turfgrasses (Jones, 1980).

Macronutrients, %		Micronutrients, ppm	
N	2.8-3.5	Fe	35-100
P	0.3-0.6	Mn	25-150
K	1.0-2.5	B	10-60
Ca	0.5-1.3	Cu	5-20
Mg	0.2-0.6	Zn	20-55
S	0.2-0.5	Mo	not known
		Cl	not known
		Ni	not known

The major shortcomings of a tissue testing program include the expense as compared with soil testing; not all testing laboratories offer the test; results may not come back as quickly as soil test results; and the lack of actual calibration tests conducted with a wide range of turfgrasses under various conditions. Until more calibration tests are completed and verified, the above sufficiency ranges should be used as relative guidelines only. Monitoring and recording turfgrass quality, clippings yield, and performance and then

relating the observations to the tissue test concentrations will help guide future fertilization and nutrient management practices once a consistent relationship is established.

Best Management Practices for Plant Tissue Analysis

- Tissue samples may be collected during regular mowing.
- Do not collect tissue after any event that may alter the nutrient analysis such as fertilization, topdressing, and pesticide applications.
- Place tissue in paper bags, not plastic.
- If possible, allow tissue samples to air-dry before mailing them.
- Poor-quality turfgrass that is of concern should be sampled separately from higher-quality turfgrass.
- When turfgrass begins to show signs of nutrient stress, a sample should be collected immediately.
- More frequent tissue sampling allows a more accurate assessment of turfgrass nutrient status changes over time.
- The frequency of tissue analysis is dependent on individual course needs. Two to four tests per year are common on greens and one to two tests per year are common on tees and fairways.
- Keeping tissue test results from prior years allows for observation of changes over time.
- Tissue testing can provide good evidence of the impact of the nutrient management plan.

Fertilizers Used in Golf Course Management

Understanding the components of fertilizers, the fertilizer label, and the function of each element within the plant are all essential in the development of an efficient nutrient management program. By law, all fertilizers include a grade or analysis stating the percent by weight of nitrogen (N), phosphorous (as P_2O_5) and potassium (as K_2O) that is a guaranteed minimum in the fertilizer. A complete fertilizer contains N, P_2O_5 , and K_2O . However, additional laws that govern fertilizer labeling vary greatly among states. Consult the land-grant university or the appropriate state agency (usually the Department of Agriculture) regarding state laws.

Label

The label is intended to inform the user about the contents of the fertilizer that, if understood and followed, will minimize environmental risk. The fertilizer label may contain the following information:

- Brand
- Size guide number (SGN)
- Manufacturer's name and address

- Guaranteed analysis/Grade
- “Derived from” statement
- Net weight

Macronutrients

Macronutrients are required in the greatest quantities and include N, P, and K. Understanding the role of each macronutrient within the plant should provide you with a greater understanding of why these nutrients play such a key role in proper turfgrass management.

Nitrogen

Nitrogen is typically the nutrient required in the greatest quantity by turfgrasses aside from C, H, and O. Concentrations of N within tissues at sufficiency levels usually range from 2% to 6% N on a dry weight basis. When turf soils do not provide an adequate amount of N, persistence, performance, and quality of the turf suffers. This is usually expressed by reduced turf growth and development, reduced shoot and tiller density, reduced stolon or rhizome growth, increased weed infestations, and a yellowing of the leaf blades that reduces visual quality and resilience to abiotic and biotic stresses. It is critical that correct amounts be supplied at appropriate times in appropriate amounts. It is easy to see when turf is lacking N, but much harder to determine when N availability is beyond adequate and excessive.

It is commonly known that N fertilization results in a darker green leaf color, but consistent excessive N fertilization for a dark green turf color may not be beneficial in the long run. Under consistent and high N rates, turfgrass health may be compromised. Excessive N availability can result in the following:

- Poor root growth because shoot growth is stimulated at the expense of the roots.
- Poor rhizome and/or stolon development resulting in a weak sod.
- Higher incidence with hot- and cold-weather diseases.
- Reduced storage of food carbohydrates needed for regrowth following stress periods and overwintering; reduced recuperative ability.
- Poor tolerance to heat, cold, traffic, and drought stresses.
- Shifts of the turf community to species that are favored by high N (e.g., annual bluegrass).
- Higher succulence resulting in less wear tolerance and disease.
- More frequent mowing.
- Higher burn potential with certain types of N fertilizers.
- Environmental and economic losses of N.

Conversely, insufficient N fertility also can negatively affect performance of turfgrasses and the environment. Adequate N fertility enables turf to resist and/or recover from abiotic and biotic stresses. Maintaining sufficient N fertilization also increases turf

density that can minimize weed infestation and the runoff of sediment, nutrients, and pesticides.

Fate and Transformation of N

The goal of all applied nutrients is to maximize plant uptake while minimizing nutrient losses. Understanding each process increases the ability to make sound management decisions and ultimately leads to an increase in course profitability and a reduction in environmental risk. Nitrogen management is more complicated than other required essential elements because of the multiple transformations that can occur in the soil with N. Nitrogen processes are shown in Figure 5-4 and include:

- Mineralization, the microbial mediated conversion of organic N into plant-available NO_3^- and ammonium NH_4^+ .
- Nitrification, the microbial-mediated conversion of NH_4^+ to NO_3^- .
- Denitrification, the microbial mediated conversion of NO_3^- to N gas (NO , N_2O , or N_2); this primarily occurs in low-oxygen environments and is enhanced by high soil pH.
- Volatilization, the conversion of NH_4^+ to ammonia (NH_3) gas; this is enhanced by high soil pH.
- Leaching, the downward movement of an element through and below the rootzone.
- Runoff, the lateral movement of an element beyond the intended turfgrass location.

Figure 5-4. Fate and transport of nitrogen in fertilizers applied to turfgrass.

Nitrogen Formulations

Nitrogen can be found in various fertilizer formulations, either as a readily available form (highly soluble in the soil solution, or fast-release) or in a slowly available form (low solubility in the soil solution, or slow-release). The fast-release forms are composed of inorganic salts such as calcium nitrate (15.5% N) and potassium nitrate (13% N) or are synthesized by reacting ammonia with various compounds to form urea (45% to 46% N), ammonium nitrate (33% to 34% N), ammonium sulfate (21% N), or mono- and diammonium phosphates (11% to 20% N).

Understanding how certain N sources should be blended and applied is an essential component in an efficient nutrient management plan. Improper application of N sources increases the risk of negative environmental impacts and economic losses. Each N source (particularly slow-release forms) is unique and therefore should be managed accordingly. Applying a polymer-coated urea in the same manner one would apply a sulfur-coated urea greatly reduces the value of the polymer-coated urea. Similarly, applying 1 pound of N from ammonium sulfate may cause burning, while applying 1 pound of N from certain polymer-coated ureas may not provide the desired turfgrass

response. Rate, application date, location, and turfgrass species all should be included in nutrient application decision-making.

Soluble Nitrogen Sources

- Urea (46-0-0)
- Ammonium nitrate (34-0-0)
- Ammonium sulfate (21-0-0)
- Diammonium phosphate (18-46-0)
- Monoammonium phosphate (11-52-0)
- Calcium nitrate (15.5-0-0)
- Potassium nitrate (13-0-44)

Table 5-10. Advantages and disadvantages of fast-release N formulations.

Fast-release N formulations	
Advantages	Disadvantages
High percentage of N by weight.	Provide only a short-term response. Effectiveness lasts only four weeks or less, which necessitates more frequent applications.
Provide an immediate response.	High salt index and a high foliar burn potential. It needs to be watered in immediately after application.
Minimal temperature dependency that provides good response under cold temperatures in spring and fall.	Higher leaching potential because of solubility.
Relatively inexpensive per unit of N.	Higher volatilization potential especially with the ammonium-containing forms.
	Higher denitrification potential especially with the nitrate-containing forms.
	Impart an acidifying effect in the soil solution.

Because of the fast-release properties, turf response from soluble N sources is often characterized by short bursts of growth after application followed by periods of slow growth as the N is rapidly depleted or lost from the soil. The process is repeated over again with each subsequent N application. The peaks and valleys in growth not only result in a greater mowing frequency shortly after application but can also quickly deplete food carbohydrates in the grass. This has a highly negative effect on root growth and gradually may cause the turf to thin out.

Slow-Release Nitrogen Sources

A slow-release N source is any N-containing fertilizer in which the release of N into the soil is delayed either by requiring microbial degradation of the N source, by coating the N substrate to delay the dissolution of N, or by reducing the water solubility of the N source. These sources include:

- Sulfur-coated urea
- Polymer/resin-coated
- Isobutylidene diurea
- Urea-formaldehyde and methylene urea (urea and formaldehyde reaction products)
- Natural organics
- Urease and nitrification inhibitors
 - Urease inhibitors reduce the activity of the urease enzyme resulting in a reduction of volatilization and an increase in plant-available N.
 - Nitrification inhibitors reduce the activity of Nitrosomonas bacteria, which are responsible for the conversion of NH_4^+ to NO_3^- . This reduced activity results in a reduction of N lost via denitrification and an increase in plant-available N.
 - Although these products improve N availability and efficiency through reduced losses, they do not necessarily reduce the rate of N needed for desired goals.

The slow-release forms of turfgrass N fertilizers are derived either by reacting urea with various organic or inorganic compounds to form urea-formaldehyde and methylene ureas (up to 38% N), IBDU (31% N), and sulfur coated urea (22% to 38% N), or are derived from natural organic materials or residues such as manure, compost, bloodmeal, food industry by-products, and biosolids.

Table 5-11. Advantages and disadvantages of slow-release N formulations.

Slow-release N formulations	
Advantages	Disadvantages
Provide more uniform turfgrass growth during the growing season and do not produce peak and valley growth.	Higher cost per unit of N.
Lower salt index and a lower foliar burn potential in most situations.	May not supply sufficient N needed by the grass.
Have a long-term turfgrass response and can carry over from year to year.	Some are more dependent on temperature for release than the fast-release forms.
Lower potential for leaching, denitrification, and volatilization losses.	
Need to be applied less frequently; and	

with the natural organic forms, they often supply other nutrients.	
--	--

Because of advantages and disadvantages of fast- and slow-release forms (Tables 5-10 and 5-11), some turfgrass fertilizers are blends of both types of N carriers to combine the advantages and reduce the disadvantages associated with each.

Specific Characteristics of Slow-Release Nitrogen Fertilizers

Urea-formaldehyde (UF) and Methylene Urea (MU) are synthesized by combining urea with formaldehyde to form a compound containing units of methylene urea. Available N from UF and MU is dependent upon microbial hydrolysis of the carrier and is temperature dependent. Solubility of these materials is based on molecular weight (chain length) of the formulation. With UF and MU, the shorter the length of subunits, the greater the solubility. The Cold Water Soluble N (CWSN) fraction of UF and MU represents the low molecular weight short chains of unreacted urea plus methylene urea that are generally more readily available. The Cold Water Insoluble N (CWIN) fraction of UF and MU represents the larger chain lengths, which have higher molecular weights and are more slowly available. The Hot Water Insoluble N (HWIN) fraction of UF represents the very large chain lengths that have very high molecular weights and are very slowly available. At 77°F, the CWSN of UF and MU is readily absorbed by turfgrasses. Typically, there is little or no response to UF and MU when applied during cold temperatures because microbial activity is minimal. A UF and MU carrier should have an active ingredient (AI) of at least 40% to supply sufficient N. Another expression of UF-N or MU -N solubilization characteristics is the urea:formaldehyde ratio. Since UF and MU are synthesized by combining urea with formaldehyde (unreacted urea plus methylene ureas with varying chain lengths), some commercial formulations are manufactured with a urea:formaldehyde ratio of 1.3:1. This provides about 25% CWSN and 75% CWIN. A more soluble formulation can be obtained with a urea:formaldehyde ratio of 1.9:1, which provides 67% CWSN and 33% CWIN. The solubility of UF and MU can be controlled by the ratio. It is desirable to have some N immediately available and the remaining made available in small amounts with time.

Isobutylidene diurea (IBDU) is formed by combining urea with isobutyaldehyde. The solubility of IBDU is not influenced by microbial activity. Instead, the availability of N is dependent on chemical rather than microbial hydrolysis. With IBDU, N release is faster with smaller particle sizes (low mass:surface area), acidic soil pH, high moisture, and warmer temperatures. Below a pH of 5, the rate of N release for IBDU is very rapid. The rate of N release from IBDU is up to three times faster at 75°F than at 50°F. Usually, there is a slower response in the spring with IBDU, but N response is faster if applied the previous fall. This allows more time for breakdown over the winter. It is common to blend different particles sizes of IBDU so that N is released over a three- to four-month period. A product with particle sizes ranging between 71 and 238 SGN mesh is best for turfgrasses.

Sulfur-Coated Urea (SCU) and Polycoated Urea (PCU) is formed when urea granules are coated with sulfur and a thin coating of sealant or polymers (wax, resins). Water diffuses in and out of micropores in the coatings until sufficient pressure builds up to cause breakage of the coating. The same factors that affect the N release of UF and ME, also affect SCU (high moisture, higher temperatures). The initial turfgrass response to SCU is fairly rapid and is faster than UF, ME, and IBDU. With SCU, there is nonuniformity in the coating thickness that provides varying release rates. It is common to blend thin-, medium-, and thick-coated granules so that N is released over six- to eight-week period or longer. The N in SCU is not defined as a Water Insoluble N (WIN) and is often listed as a Controlled Release N (CRN) and characterized by a seven-day dissolution rate value. The seven-day dissolution rate value is the percent of N released from SCU in water at 95°F in one week under laboratory conditions. Most commercial SCU formulations have a seven-day dissolution rate of 20% to 30%. This means that 20% to 30% of the N is quickly released and 80% to 70% of the N is slowly released. A dissolution rate below 20% indicates a material with N that is probably too slowly available for most turf purposes and a dissolution rate above 30% indicates a material that would not be considered a slow release N source. Various polymer-coated urea products are available. These materials control the release of N by diffusion through a polymer membrane that coats the urea. Release rates are dependent on moisture, temperature, and coating's composition and thickness.

Fertilizers Derived from Organic Materials are derived from natural organic sources. These materials are typically lower in N and usually more expensive per unit N than synthetically derived products, but they offer many advantages for use on turfgrass:

- Low potential for foliar burn.
- Low leaching and volatilization potential.
- Slower acidifying effect on soil pH.
- Wide range of both macro- and micro-essential elements.
- Potential improvement of the physical properties of turf soil.

Release of N from organic fertilizers is dependent on microbial activity. Depending on conditions, N release from organic fertilizers can be relatively rapid or may be immobilized within the soil organic matter and not released for months.

Nitrogen Fertilizer Programs

Frequency and intensity of fertilization depends on many factors:

- Species. Less fertility is required for the fine leaf fescues, common types of Kentucky bluegrass, tall fescue, and bentgrasses. Higher fertility is required for improved types of Kentucky bluegrass, perennial ryegrass, and annual bluegrass. Annual bluegrass populations can increase under higher N fertility at the expense of bentgrass (Dest and Guillard, 1987).
- Environmental conditions. Shaded turf requires less N than turf growing under full sun conditions. Reduce N rates by one-third to one-half in shaded areas. Higher

precipitation and irrigation rates increase the amount of N lost through leaching and denitrification, therefore more frequent fertilizer application may be required. If high rates of N are applied to cool-season turfgrass during high temperatures, shoot growth will be rapidly stimulated, reducing food carbohydrates and negatively affecting root growth. Disease susceptibility also increases. Turf decline may follow.

- Soil characteristics. Sandy soils and sand-based rootzones require more frequent fertilizer applications than soils with more clay and silt. Soils with higher organic matter content or more clay and silt require less fertilizer than sandy soils or soils with lower organic matter content.
- Maturity of turf stand. There is a greater fertility need for turf at establishment and less so as the stand matures. As turf matures, there is a greater potential for N losses because the storage potential of the soil organic matter is maximized. Therefore, less N is required on older mature stands of turf than younger, newly established stands of turf.
- Length of growing season. The longer the growing season, the more that nutrients are required to sustain turf growth and quality.
- Mowing height. As mowing height is lowered, individual shoots become smaller and turf density increases. Therefore, smaller amounts of N fertilizer should be applied because higher rates may burn the leaves due to collection of fertilizer on the denser leaf surface.
- Clipping management. Returning clippings to the turf markedly reduces fertilizer needs. On higher-cut turf, UConn studies indicate that N fertilizer rates can be reduced by 50% or more without a loss in turf growth and quality when clippings are returned (Kopp and Guillard, 2002). Contrary to popular belief, grass clippings do not contribute to thatch and are mostly decomposed (>80%) within eight weeks after being returned to the turf (Kopp and Guillard, 2004).
- Traffic and wear. Trafficked golf turf will require more frequent applications of N to recover from traffic and wear.

Because of the different variables, turfgrass fertilization programs are site specific. Therefore, it is important for the turf manager to evaluate each site and its particular combination of features before initiating a fertilization program.

Nitrogen Fertilization

Frequency An ideal turfgrass N fertilization program consists of frequent applications of very small amounts of nutrients during the growing season to meet growth requirements without overapplication. With such a program, the turf manager can meet nutrient needs quickly. The term “spoon feeding” is used for these types of fertilization programs. Nutrients such as N are applied at rates of approximately 0.10 to 0.25 lb N/1,000 ft²/application or less during the season at seven- to 21-day intervals. For most golf courses, spoon feeding is applicable to the lower-cut turf. For higher-cut turf (roughs and other amenity areas), infrequent N applications (one to three times per year) at higher rates are appropriate.

Nitrogen Fertilization Rate

[Click here to view the Vermont fertilization recommendations, by Dr. Sid Bosworth.](#)

(Page 4 is where the Nitrogen Recommendations can be found)

The maximum amount of N that may be safely applied at any one time depends on the form and carrier of N, temperature, time of year, mowing height, species, and turf use. Here are examples of application rates:

- Under favorable conditions in New England, soluble N-containing fertilizers can be applied on short-cut turf at 0.10 to 0.25 lb N/1,000 ft²/application. For higher-cut turf, N should be applied to provide no more than 1 lb N/1,000 ft² in any one application. Apply soluble N-fertilizers only when turf is dry and when temperatures are below 80°F. After application, apply water to wash the fertilizer off the foliage. Under hot temperatures, higher rates of soluble N may cause burn or excessive shoot growth.
- Under hot temperatures, N application should be avoided or limited to no more than 0.10 lb N/1,000 ft²/application on lower-cut turf, and 0.5 lb N/1,000 ft² in any one application for higher-cut turf.
- With the natural organic materials, slightly higher rates may be used. However, no more than 1 lb N/1,000 ft² on lower-cut turf and no more than 3 lbs N/1,000 ft² on higher-cut turf should be applied at any one time. Reduce the number of applications by half when natural organic sources are applied at rates greater than 1 lb N/1,000 ft².
- In New England, an annual total of 2 to 3 lbs N/1,000 ft² is usually sufficient for good growth of short-cut turf. For higher-cut turf, up to 2 to 4 lbs of N/1,000 ft² per year is often applied. Reduce rates when clippings are returned.

Nitrogen Fertilization Timing

Fertilizer applications should be timed to maximize growth and vigor in the grass plant. Key times to apply fertilizer are spring, late spring, late summer, or early fall. Timing of fertilizer application should be based on environmental conditions and coincide with turfgrass needs. Therefore, time fertilizer application to provide nutrients at the beginning of periods when temperature and moisture conditions favor active turfgrass growth. Higher rates of N fertilization should be avoided when turf is stressed or with shaded turf. Summer application of fertilizer is generally not recommended unless recovery is required from traffic or wear, or where spoon-feeding programs are implemented. Excessive midsummer N fertilization promotes certain hot-weather diseases such as brown patch, summer patch, and pythium. It also stimulates shoot growth at a low-growth period, which depletes the food carbohydrates in the grass. This reduction in carbohydrates is detrimental to root growth. A rapid reduction in root growth leads to decreased heat, drought, wear, and pest tolerance.

Late-season N fertilization for cool-season turfgrasses has been advocated anywhere from mid-September to mid-December to promote root growth, better color retention in

the fall, and earlier green-up in the spring. Late-season N fertilization of cool-season turfgrasses has become a well-established management practice in the Northeast. The rationale behind this practice is based on the beneficial physiological and rhizome/rooting responses of turfgrasses during this period to the applied N.

The positive response of turfgrass to late-season fertilization is physiologically based and related to energy partitioning within the grass plant under decreasing photoperiods and temperatures.

- During the fall, air temperatures are not optimum for shoot growth but soil temperatures are ideal for root and rhizome growth. However, N from fall fertilization enables the turfgrasses to retain leaf color (chlorophyll content) into late fall and, as a result, higher levels of photosynthesis are sustained. Because air temperatures are not conducive for shoot growth at this time, the energy produced is used for root/rhizome growth.
- Higher photosynthetic rates and minimal shoot growth in the fall maintain higher storage carbohydrate reserves in the roots. High levels of carbohydrate reserves in the roots enhance winter survival and spring recovery. This enhanced carryover effect on spring green-up and growth substantially diminishes the need for early season N, which would stimulate top growth at the expense of root development.
- Other reported beneficial effects of late-season fertilization are turf that is more vigorous and less susceptible to diseases during spring re-growth, and turf that enters the summer heat period in a more hardened, healthy state.

Although agronomic benefits of late-season N fertilization are reported, caution should be used with this practice with respect to N losses from runoff and leaching. Leaching losses of soluble forms of N are much higher during this time of the year than during the active growing season. Also, cool-season turfgrass species and cultivars differ substantially in their N uptake and use efficiencies. Fall or winter fertilizer application might further enhance the leaching potential of some grasses that inherently express poor N-use efficiency. Research conducted at the University of Connecticut indicates that a greater potential exists for nitrate leaching losses with soluble N-based fertilizers than with slow-release or natural organic fertilizers when applied after October 21 (Guillard and Kopp, 2004). Also, leaching losses of up to 66% for soluble N sources when applied to higher-cut turf have been observed in mid-October and later applications (Mangiafico and Guillard, 2006).

Heavy spring applications of N to turf are also not recommended. Heavy application of N in early to mid-spring on cool-season turf may encourage more severe incidence of spring and summer diseases and may reduce root development. During the winter, stored food carbohydrates (energy sources) are utilized by the grass for maintenance. Because environmental conditions do not favor rapid replenishment through photosynthesis during the winter, the grass plant enters a very vulnerable position by the time spring re-growth is required. Energy stores are at their lowest levels and excessive demands for energy by growth can severely weaken the grass. Heavy N

applications in the spring stimulate very rapid shoot growth at the expense of the roots. This results in a weakened turf that is more susceptible to stresses and pests and thins out during the summer.

Phosphorus

[Click here to view the Vermont fertilization recommendations, by Dr. Sid Bosworth.](#)

(Page 4 & 5 is where the Phosphorus Recommendations can be found)

Turfgrasses take up P primarily as orthophosphate (H_2PO_4^-). Phosphorus forms high-energy compounds that are used to transfer energy within the plant. Although many mineral soils contain relatively large amounts of P, it occurs in forms not available to turfgrass plants. Phosphorus is readily fixed by Ca, Fe, or Al. At a pH below 5.5, Fe and Al form an insoluble complex with P that makes P less available to turfgrass. At a pH above 7.5, Ca complexes with P to form an insoluble complex that makes P less available to turfgrass. It is commonly believed that P is most available to turfgrasses when soil pH is between 6 and 7.

Because phosphorus is a major contributor to eutrophication of waterbodies, proper timing and rates of application should be used to reduce the risk of off-site movement of phosphorus.

The role of P in turfgrass culture is important in seed germination, seedling vigor, and rooting responses. Therefore, P is critical during turfgrass establishment. Fertilization of P should be based on soil tests or tissues tests. When establishing new turf, P should be applied when extractable P levels in a soil test indicate a need. The P-containing fertilizer should be incorporated into the soil before seeding or sodding to a depth of 4 to 6 inches to provide at least 2 lbs P_2O_5 /1,000 ft². On low P sites, the new seedlings or sod should be additionally topdressed to provide at least 1 lb P_2O_5 /1,000 ft² after emergence. With tissue tests, adequate P is available when leaf P concentrations are 0.2% or above on a dry weight basis. For mature turf, P should be applied as a maintenance fertilizer only when soil test extractable P levels read low to provide at least 1 lb P_2O_5 /1,000 ft².

A single application usually provides sufficient P for turfgrass growth for a growing season. There is little turfgrass response to P fertilizers when extractable P levels are medium or above. Continual fertilization of soils testing medium or above for extractable P will result in high soil test P values with no added beneficial responses for turf. High soil test P levels increase the potential for annual bluegrass infestations on short-cut golf turf, leading to a decrease in bentgrass populations. Soils testing high in extractable P also increase the potential for nutrient contamination of surface and ground water by P that leaches or runs off turf.

Fertilization with P is often dependent on N rates. Low maintenance turf with low N input will probably not require much, if any, P fertilization. Under higher N inputs with clippings removed, however, P fertilization may be required. If clippings are returned to

the turf, there may be little need to fertilize with P. The residual supply from previous or initial P applications in addition to the recycling of P from the clippings may be adequate for turfgrass needs, provided that the soil pH ranges between 6 and 7. Phosphorus deficiency symptoms initially include reduced shoot growth and dark green color; later, lower leaves may turn reddish at the tips and then the color may progress down the blade.

Most P fertilizers are derived from rock phosphate ores treated with mineral acids. Superphosphate is derived from rock phosphate treated with sulfuric acid to form calcium phosphate and gypsum. Triple superphosphate is derived when rock phosphate is treated with phosphoric acid to form calcium phosphates. Ammonium phosphates are derived when ammonia is treated with phosphoric acid to form mono- and diammonium phosphates.

- P fertilizer sources
 - Superphosphate (SP) – $\text{Ca}(\text{H}_2\text{PO}_4)_2$; 20% P_2O_5
 - triple superphosphate (TSP) – $\text{Ca}(\text{H}_2\text{PO}_4)_2$; 46% P_2O_5
 - Monoammonium phosphate (MAP) – $(\text{NH}_4)(\text{H}_2\text{PO}_4)$; 52% P_2O_5
 - Diammonium phosphate (DAP) – $(\text{NH}_4)_2\text{HPO}_4$; 46% P_2O_5
 - Natural organics

Potassium

[Click here to view the Vermont fertilization recommendations, by Dr. Sid Bosworth.](#)
(Page 4 & 6 is where the Potassium Recommendations can be found)

Turfgrasses take up large amounts of K as the cation K^+ . Turfgrass leaf concentrations of K can range from 2% to 5% of the dry matter. High K concentrations in turfgrass leaf tissue have been reported to improve tolerance of heat, drought, cold, disease, and wear. It is common to see high-K containing turf fertilizers, which are often called winterizers, promoted for late-season application. However, the effects of high K applications have been inconsistent and not observed in all cases.

Fertilization of K should be based on soil tests or tissues tests. Potassium should be applied only when the soil test extractable levels are low and at a rate to provide at least 1 lb K_2O /1,000 ft^2 . Tissue concentrations below 1% are considered deficient (Jones, 1980) and a N:K ratio of 2:1 in the tissue is considered optimum. There is little turfgrass response to K fertilizers when soil test extractable K levels are medium or above. Potassium is a constituent of many soil minerals and weathering of nonexchangeable forms may provide a significant amount of K to turfgrasses in New England soils during the growing season. In southern New England studies, no positive growth or quality effects have been reported (Dest and Guillard, 2001; Fitzpatrick and Guillard, 2004; Ebdon et al., 2013). Likewise, there has been little to no effect found in wear tolerance and traffic recovery (Hoffman et al., 2010). However, K fertilization beyond what is recommended for optimum shoot growth may increase the winter hardiness of annual bluegrass (Schmid et al., 2016) and perennial ryegrass (Webster and Ebdon, 2005).

If clippings are returned to the turf, probably little if any need to fertilize with K exists. In addition to clipping management, fertilization with K often depends on N rates. Low-maintenance turf with low N input will probably not require K fertilization. Release of nonexchangeable K from soil minerals will probably be sufficient to meet turfgrass needs under these conditions. However, under higher N inputs with clippings removed, K fertilization may be required if clippings are removed over many years. When K fertilization is needed under these situations, it is typical to use a N:K fertilizer ratio of 1:1.

Most K-containing fertilizers are derived from potassium salts such as muriate of potash (KCl, 60% K₂O). Combining KCl with sulfuric acid forms potassium sulfate (50% K₂O), whereas KCl combined with nitric acid forms potassium nitrate (44% K₂O). Muriate of potash has a higher burn potential (salt effect), but is fast acting and less expensive than most other K-containing fertilizers. Potassium sulfate is slower acting and more expensive than KCl and produces an acidifying effect in the soil, but has a lower burn potential than KCl. Potassium is susceptible to leaching in sandy soils with low CEC. Therefore, overwatering of turf should be avoided to maintain adequate levels and reduce loss of K in the soil.

- K deficiency symptoms

Except under severe, documented deficiencies, K may not have an observable influence on turfgrass quality. Yellowing of older leaves followed by tip dieback and scorching of leaf margins have been reported.

- K fertilizer sources
 - Potassium sulfate – K₂SO₄; 54% K₂O
 - Potassium chloride – KCl; 60% K₂O
 - Potassium nitrate – KNO₃; 46% K₂O

Best Management Practices for Fertilization

- Apply nutrients when turfgrass is actively growing.
- Apply N at rates and intervals to maintain moderate turf growth and recuperative potential.
- Use light, frequent N applications (spoon-feeding) to provide turf consistent nutrition and minimize potential for leaching and runoff.
- Apply slow-release N fertilizer at the appropriate time of year to maximize the products' release characteristics.
- N application rates from slow-release materials should take into consideration the release rate of the chosen material.
- Select a N:K fertility ratio based on turf use, rootzone, and clippings management.
- Exercise caution when applying nutrient applications during turfgrass establishment as these applications are particularly susceptible to loss via leaching and runoff.

- Provide appropriate rates and products to minimize N loss without reducing turfgrass establishment.
- Be aware of the different types of spreaders and understand the advantages and disadvantages of each.
- Calibrate spreaders regularly to reduce environmental risk and increases profitability. FertAdvisor is a free smartphone application that assists in spreader calibration developed by the University of Connecticut and available for both iPhone and Android users.
- Reduce environmental risk by properly storing and loading fertilizer and cleaning up any spills.
- Avoid applying fertilizer to soils that are at, or near, field capacity or following rain events that leave the soils wet.
- Do not apply fertilizer when the National Weather Service has issued a flood, tropical storm, or hurricane watch or warning, or if heavy rains are likely.

Soil pH

Maintaining soil pH within certain tolerances plays an important role in turfgrass growth and quality. Nutrient availability and soil flora and fauna activities are closely associated with the pH of the soil. These activities are important for mineralization of soil organic matter, thatch, and grass clipping decomposition, severity and incidence of certain turfgrass pests, and influences on pesticide efficacy. Liming does not replace a sound fertilization program, but enhances one. Therefore, the turfgrass manager must understand and appreciate how pH influences the persistence, growth, and quality of turf.

Soil pH is the result of the chemical reactions that occur in the soil, and these reactions affect the degree of acidity or alkalinity of a soil solution. The pH scale is used to measure the effects of these soil reactions. This scale is related to the amount or concentration of hydrogen ions $[H^+]$ present in the soil solution, and then transformed into a value that is easily understood. Mathematically, the pH value is calculated as the negative logarithm (base 10) of the hydrogen ion concentration $[H^+]$, and ranges from 0 to 14.

Because the scale is measured using logarithms (base 10), it increases or decreases 10 times for each unit change of pH. For example, even though a pH of 5 does not seem that much lower than a pH of 6, the pH of 5 is 10 times more acidic than the pH of 6. A pH of 4 is only two units lower than 6, but 100 times more acidic.

Soil pH varies throughout New England, but most turfgrass soils are in the pH range of 5.0 to 7.0. The soil pH is usually a function of precipitation in which greater precipitation or irrigation induces more leaching of Ca^{+2} , Mg^{+2} , and K^+ , which are replaced by acidic H^+ or Al^{+3} ions. Soils of New England, which are located in a humid region of the country and receive 40 to 50 or more inches of precipitation yearly, generally have acidic soils.

Other factors also influence soil pH. The underlying parental material from which soil is formed will affect pH. Most soils of New England are formed from gneiss, schist, or granite that are naturally acidic. Soils high in organic matter also tend to have an acidic pH because organic acids are released from the organic matter as it decomposes. Fertilization practices may also affect soil pH. Nitrogen applications generally have an acidifying effect (especially the NH_4 -based formulations) because H^+ ions are released when NH_4 is reduced to nitrate (NO_3) in the soil solution.

Optimum Ranges of Soil pH for Turfgrasses

Although most turfgrasses can tolerate a wide range of soil pH values, a pH range of 6 to 7 is generally recommended for New England turf. Kentucky bluegrass, a popular turf species, does best when soil pH is between 6.5 and 7.2. Ryegrasses and bentgrasses are somewhat more tolerant of lower soil pH values than Kentucky bluegrass, but they also perform best under a neutral or slightly alkaline pH. The fine fescues and turf-type tall fescues can tolerate fairly acidic soil conditions, but their growth is also better under a neutral or slightly alkaline pH.

At extreme pH values, certain essential elements become less available and others become more available (excessive). Many of the micronutrients remain available at acidic pH, which can create problems with Al and/or Mn toxicities. At acidic pH, there is also a decrease in microbial, earthworm, and other soil flora and fauna activities. This results in a decrease in mineralization and decomposition of organic matter, a potential loss of favorable soil structure, and excessive thatch buildup.

Liming Materials

When soil pH is acidic, the turf manager needs to neutralize the soil acidity by adding liming materials. The most common liming materials are:

- Calcitic limestone (calcite) - calcium carbonate (CaCO_3), which is 40% Ca and called agricultural grade limestone.
- Dolomitic limestone (dolomite) - $\text{CaMg}(\text{CO}_3)_2$, which is 27% Ca and 13% Mg and also called agricultural grade limestone.
- Pelletized Lime - small limestone particles in pellet form. This reduces dust and makes spreading easier. It dissolves rapidly into powder when it comes into contact with water. This is generally the most common form of liming materials used on golf courses.
- Burned lime or Quicklime - CaO or MgO , which has the fastest reaction in the soil but can burn the turf if applied incorrectly. It is caustic to handle and more expensive than ground limestone. Typically not recommended for turfgrass.

- Hydrated lime or Slacked lime — $\text{Ca}(\text{OH})_2$ or $\text{Mg}(\text{OH})_2$ which is fast acting but also caustic to handle. It is more expensive than ground limestone and can react with ammonia-containing fertilizers to form ammonia gas that is toxic to grass. Therefore, this material should not be applied with fertilizers at same time. Wait at least two weeks between applications of fertilizer and hydrated lime. Typically not recommended for turfgrass.
- Calcium sulfate (gypsum, CaSO_4) or magnesium sulfate (Epsom salts, MgSO_4) has no effect on pH, but can supply Ca, Mg, or S.

Rates of Lime Application

Soil tests are the only way to determine if the turf soil requires lime. The rate for liming materials is partly determined by soil texture. Soils with more clay and silt require more lime to neutralize acidity than sandier soils. Soils with higher organic matter may require more lime than the same soil type with lower organic matter content.

Because most New England soils contain an appreciable amount of sand, it is best to limit each application of ground limestone to 50 lbs/1,000 ft² when applied to established turf. Higher rates may result in excessive alkalinity near the soil surface before the lime eventually moves downward. This is especially the case with turf containing a thick thatch layer. If more than 50 lbs limestone/1,000 ft² are recommended based on a soil test, the applications should be split at least a few months apart. When establishing new turf, the total limestone requirement may be applied in a single application provided that it is thoroughly mixed into a 4- to 6-inch depth before seeding or sodding.

Lime Moves Slowly Through the Soil

Lime moves slowly downward in the soil profile at a rate of about 0.5 to 1 inch per year, but not laterally. Surface applications can take two or more years to increase the pH of the rootzone to proper levels. Therefore, the pH must not be allowed to drop too low before adding lime.

Soil tests for pH are recommended every two years. Lime should be added if the pH drops to 6 or below. Lime is generally best applied in the fall so that it can be worked into the soil by freezing and thawing action and has sufficient time for reaction before active regrowth of turf in the spring. Applying lime after core aeration helps move lime more quickly into the rootzone.

Correcting Soil Alkalinity

If a soil test shows the soil pH above 8 in a turfgrass system, then it must be lowered. Often, this is a result of overliming of sandy soils. The excess sodium (Na^+), Ca^{+2} , Mg^{+2} ions form insoluble complexes with the micronutrients that may induce micronutrient deficiencies. In these situations, the application of sulfur at rates of 3 to 5 lbs/1,000 ft²

should decrease pH to more favorable levels. Sulfur can be applied as elemental S, ammonium sulfate, iron sulfate, or potassium sulfate. Calcium sulfate (gypsum) or magnesium sulfate (Epsom salts) have little effect on soil pH and should be avoided for purposes of lowering soil pH.

Best Management Practices for Soil pH

- Maintain pH near 6.8 to optimize nutrient availability and reduce fertilization requirements.
- To increase soil pH, apply a liming material (calcium carbonate, calcium oxide, dolomitic limestone) that contains Ca^{2+} or $\text{Ca}^{2+}/\text{Mg}^{2+}$ and neutralizes acidity.
- To lower soil pH, products containing elemental sulfur should be applied.
- In some cases, utilizing injection pumps into irrigation water to address pH can be beneficial.

Cultural Practices

Preface

Cultural practices play a large role in turfgrass quality. In addition to selecting appropriate turfgrass species or cultivar, proper cultural management can help produce a dense, healthy playing surface. These practices are used on all areas of a golf course, including putting greens, fairways, tee boxes, and roughs and include a variety of methods, such as mowing, cultivation, cultivar selection, and rolling. These practices typically manage the top 3 to 4 inches of soil and improve nutrient and water uptake and the overall health of the plant.

Turfgrass Selection

Selection of turfgrass species or cultivar is one of the most important decisions a manager can make to ensure a healthy turfgrass stand. Selecting the wrong species can lead to turfgrass failure, resulting in poor density, poor playability, increased water use, and increased likelihood of pesticide application. Turfgrass managers should select grass species and cultivars based on the existing site conditions and the intended use of the turf. Criteria include the selection of:

- Drought-tolerant species and cultivars where water is limited or not available.
- Wear- and compaction-tolerant species and cultivars for heavy play and high traffic areas.
- Disease-tolerant and endophytic cultivars to reduce pest damage and pesticide use.
- Shade-tolerant species and cultivars for areas with limited or restricted light.

Breeding programs have made tremendous advances in the development of improved turfgrass cultivars. Within each turfgrass species, cultivars can now be selected for improved characteristics such as denser playing surfaces, tolerance of lower mowing heights, increased drought tolerance, improved wear tolerance, improved pest resistance, improved shade tolerance, and improved salinity tolerance. As a result of these improvements, managers can select cultivars or species appropriate for the site that require less water, pesticide, and fertilizer.

When planning new seeding or overseeding projects for the golf course, it is recommended that turfgrass mixtures (two or more species) or blends (two or more cultivars of the same species) be used to improve genetic diversity of the turfgrass stand. Consideration should be given to match turfgrass characteristics such as color, texture, growth rate, and mowing height requirement of grasses in the mix or blend. Examples of typical grass species and blend or mixture recommendations for cool-season grasses in New England can be found in Table 6-1.

Table 6-1. Recommended turfgrass species for New England Golf Courses

Area of Golf Course	Species	Recommended Mixture or blend
Putting Greens	Creeping bentgrass	Single Cultivar ¹ or Blend
	Velvet bentgrass	Single Cultivar ¹ or Blend
Tees and Fairways	Creeping bentgrass	Blend
	Perennial Ryegrass	Blend
	Compact Kentucky bluegrass	Blend
	Compact Kentucky Bluegrass/Perennial ryegrass	Mixture
	Compact Kentucky Bluegrass/Fine fescue	Mixture
	Fine leaf fescue/colonial bentgrass ²	Mixture ² Minimally irrigated areas
Roughs³	Kentucky bluegrass	Blend
	Kentucky bluegrass/ Perennial Ryegrass/fine fescue	Mixture
	Turf-type Tall fescue ⁴ (minimally irrigated roughs)	Blend

When considering new turfgrasses, managers can consult the [National Turfgrass Evaluation Program](#), the [Alliance for Low-input Sustainable Turf](#) (A-List Turf), or the [Turfgrass Water Conservation Alliance](#) to select cultivars that perform well in their region. Attending educational conferences, seminars, and turfgrass field days are other ways turfgrass managers can learn about new and improved cultivars (Figure 6-1).

Figure 6-1. National Turfgrass Evaluation Program fine fescues traffic trial for University of Connecticut. The study evaluated the use of low input (low water and fertility) for fine fescue species and cultivars maintained at golf course fairway mowing heights.

Best Management Practices for Turfgrass Selection

- Identify site characteristics and use requirements that may impact turfgrass growth and performance.
- Select appropriate grass species and improved cultivars for the site and intended use with the following characteristics as needed:
 - Lower mowing height of cut
 - Increased density
 - Improved shade tolerance
 - Improved heat tolerance
 - Improved drought tolerance
 - Reduced disease susceptibility
 - Reduced insect susceptibility
 - Improved traffic (wear + compaction) tolerance

Mowing

Mowing is the most common cultural practice of managed turfgrass systems. Turfgrasses are unique in that they tolerate routine mowing at heights from 0.09 to 4 inches depending on the turfgrass species and/or cultivars. When considering mowing, five areas of interest affect turfgrass quality and playability: height of cut (HOC), mowing frequency, clipping management, mower selection, and mowing direction. Additionally, the type of roller (i.e. smooth or grooved) on the front of the mower can also affect mowing quality.

Mowing Height

Turfgrass HOC is determined by several factors, including, but not limited to, the following: species and cultivar, area of play (tee, green, fairway, etc.), budget, number of rounds, and tournament or non-tournament conditions. Examples of typical mowing heights and desirable ranges for New England golf turfgrass, are provided in Table 6-2. In general, no more than 30% to 40% of the leaf blade should be removed in a single mowing (Crider, 1955). On turf stands that have been previously maintained at a higher mowing height, or turf that has not been mowed for an extended length of time (i.e. too wet to mow), the HOC should be lowered gradually and in weekly intervals.

Table 6-2. Mowing heights* commonly utilized for golf course playing surfaces in New England

Species	Greens Regular Membership play	Greens Tournament conditions	Collars, Tees, and Approaches	Fairways	Rough (primary)
	----- inches -----				
Creeping bentgrass	0.1 - 0.14	0.09 - 0.125	0.25 - 0.4	0.35 - 0.5	-
Velvet bentgrass	0.1 - 0.14	0.09 - 0.125	0.25 - 0.4	-	-
Perennial ryegrass	-	-	0.4 - 0.5	0.4 - 0.5	1.5 - 3
Kentucky bluegrass **	-	-	0.5	0.5 - 0.14%	1.5 - 3
Fine Fescue	-	-	0.4 - 0.5	0.4 - 0.5	-
Tall fescue (turf-type)	-	-	-	-	1.5 - 3

Mowing heights may need to be adjusted based on weather conditions, time of year, turfgrass health, the presence of abiotic or biotic stresses, and the growing environment. For example, mowing HOC should be raised for turf grown under shade conditions. Doing so allows for increased leaf area that maximizes photosynthesis (Gardner and Goss, 2013).

Maintaining an optimal root-to-shoot ratio is critical for plant health. Mowing at an HOC less than the desirable range negatively affects the plant (Figure 6-2). Lower mowing heights often result in decreased root growth (Liu and Huang, 2002) as well as decreasing rhizome production (Juska et al. 1955). When this occurs, drought tolerance is reduced, susceptibility to root-feeding insects and pathogens can potentially increase, and overall plant vigor decreases (Steinke and Ervin, 2013). Turfgrasses maintained

below their optimum HOC can also result in increased weed pressure (Calhoun, et al. 2005). To maintain plant health when mowing turfgrasses below their range of adaptation, greater inputs of water, fertilizer and pesticide may be needed.

Figure 6-2. Operator error resulted in scalped turf.

Mowing Frequency

Mowing frequency is primarily a function of mowing height. Turf maintained at lower mower heights should be mowed more frequently to avoid removing too much leaf tissue in a single cutting. Frequent mowing increases shoot density and tillering, which can improve playability.

Mowing frequency has been shown to have an impact on root to shoot ratios. Krans and Beard (1985) reported that root:shoot ratios were greater for Merion Kentucky bluegrass plants that were clipped semiweekly compared with plants that were cut weekly or biweekly. Mowing strategies that can help maintain optimal root to shoot ratios are as follows:

- When possible, reduce mowing frequency when grasses are suffering from biotic or abiotic stresses, or from mechanical damage as a result of cultural practices.
- Do not remove more than 30% to 40% of the leaf area with a single mowing (Crider, 1955). In order to follow this rule, mowing frequency should be based on factors such as time of year, fertility level, water availability, and, ultimately, the rate of grass growth.

Mowing Equipment

Reel and rotary mowers are the two main types of mowers used on the golf course for maintaining areas of play (Figures 6-3 and 6-4). Quality of cut for both reel and rotary mowers depends upon sharp, well-adjusted blades. Dull blades increase the likelihood of wounding leaf tissue, increased water loss, and increased potential for infection or

disease (Figure 6-5). Reel mowers provide the best quality of cut at mowing heights less than 1.5 inches. Generally, the lower the HOC the more blades there are on the reel cylinder. The combination of the number blades on the reel, the reel speed (rotational velocity), and the forward speed of the mower make up the clipping rate. It is critical that the clipping rate matches the HOC to provide the most uniform playing surface. Rotary mowers provide acceptable mowing quality when used at mowing heights equal to or greater than 1 inch.

Figure 6-3. Reel mowers are used on greens, collars, tees, approaches, and fairways. Proper reel to bed knife adjustment is necessary to maintain plant health.

Figure 6-4. Rotary mowers are used for rough and surrounds (bunker, green, and tee). Sharp rotary blades are necessary for a quality cut and plant health.

Figure 6-5. Dull mower damage to turfgrass. Properly adjusted mowers minimize turf stress.

Clipping Management

Turfgrass clippings are a source of nutrients. Research has shown that nitrogen fertilization rates can be cut by as much as one-half when clippings are returned (Kopp and Guillard 2002). Therefore, clippings should be returned to the site during the mowing process unless the presence of grass clippings will have a detrimental impact on play. Other times that clippings should be removed are during disease outbreaks, when practicing *Poa annua* control strategies (Gaussoin and Branham, 1989), or when weed seed production is high.

In areas where clippings cannot be returned, such as putting greens, they may be collected and either composted for future use or dispersed in areas such as roughs or practice ranges. On fairways and tees, clippings can be dragged back into the turf canopy with the use of a metal chain pulled between two golf carts or blown into the rough (Figure 6-6). Because nutrients contained in clippings can be a source of pollution, they should be handled properly and care taken to avoid depositing clippings into wetlands, ponds, and streams.

Figure 6-6. To return nutrients back to the soil, collected clippings should be composted, blown, or spread into roughs and out of play areas on the golf course.

Rolling

Rolling putting greens has proven to be beneficial in maintenance programs (Figure 6-7). It provides for a smoother (“truer”) putting surface and increases putting green speeds. Both benefit playability. Rolling allows managers to either reduce mowing frequency or raise mowing heights while maintaining acceptable putting green speeds. Rolling has also been shown to reduce incidence of dollar spot (Nikolai et al., 2001). To reduce the potential of compaction, rolling should be avoided when soils are saturated.

Figure 6-7. Rolling putting green surfaces can allow managers to reduce mowing frequency or raise mowing heights while maintaining putting green speeds.

Best Management Practices for Mowing

- Maintain turfgrass mowing heights within the ranges of adaptation for the species and cultivars being grown.
- Avoid removing more than 30% to 40% of the total leaf area in a single mowing.
- Reduce mowing frequency when turf is suffering from biotic and abiotic stresses.
- Alternate between rolling and mowing when turf shows signs of stress.
- Increase mowing height and roll greens routinely (e.g., every other day) to maintain ball roll distance and turf health.
- Properly adjust mowers and sharpen blades to maintain mowing quality and reduce the possibility of disease or infection through wounded plant tissue.
- Return clippings to the turf when possible and account for the nutrients they contribute to the fertility program.
- Remove clippings during periods of weed seed production, to reduce disease spread, to eliminate potential smothering of turfgrass plants from excessive clipping volume, or when clippings interfere with functional use of the turf.
- Do not dispose of or compost clippings near ponds, streams, and waterways or on impervious surfaces.

Cultivation

Turfgrasses are unique in three ways: they tolerate frequent close mowing; they persist under traffic conditions; and they form a dense, contiguous community. These characteristics make turfgrasses ideal for functional outdoor spaces like golf courses. However, high traffic areas such as fairways, tees, and putting greens can deteriorate with routine use.

The negative impacts of soil compaction and high wear will be evident in concentrated traffic areas. Thatch accumulation can be problematic in less trafficked areas. The surface of the soil profile (top 3 inches) needs to be actively managed to enhance turfgrass health by improving water movement, increasing atmospheric gas exchange, reducing root penetration resistance, and removing thatch accumulation. Accumulation of excessive thatch and organic matter will reduce root growth, reduce water infiltration, cause scalping, create an undesirable playing surface, and encourage disease and insect activity.

Cultivation involves disturbing the thatch and/or soil through the use of various methods such as hollow-tine cultivation, solid-tine cultivation, slicing, spiking, water injection, air injection, verticutting, drill aerification, and deep-tine cultivation (Figure 6-8).

Depending on equipment used, goals, and turfgrass growth rate, cultivation techniques can result in disturbance of the playing surface that can require significant time for recovery. The level of disruption depends on the type of cultivation selected. Type and frequency of cultivation should be based on traffic intensity, growing conditions, degree and depth of soil compaction, and the amount of thatch accumulation.

Figure 6-8. Solid, deep-tine aerification on a croquet court (left) and an aggressive fairway verticutting (right).

Best Management Practices for Cultivation

- Conduct more aggressive techniques such as hollow-tine cultivation only when grasses are actively growing to aid in quick recovery of surface density (typically during or just before periods of rapid root growth such as spring and fall).
- Design core cultivation programs to remove 15% to 20% of the surface area per year on sand-based putting greens. This typically will require two core cultivation treatments annually.
- Vary depth of aerification events every two to three years to prevent compacted subsurface layers in the soil profile. This can include varying the length of tines used, but ideally deep-tine equipment that can reach depths of 6 inches or more should be used.
- Use less aggressive types of cultivation such as small solid tines (needle tines), water injection, or air injection during more environmentally stressful periods to vent the surface (maintain gas exchange) and maintain infiltration rates (Murphy and Rieke, 1994; Carrow, 2003).
- Conduct shallow vertical mowing (blades do not penetrate the soil surface) monthly to prevent thatch accumulation and stimulate new growth to increase shoot density by cutting stolons.
- Only use more aggressive vertical mowing (blades reach the bottom of the thatch layer into the immediate soil surface) as a curative approach for thatch removal once the thatch layer reaches a 0.25 inch depth.
- Apply sand topdressing concurrently with more aggressive forms of cultivation such as hollow-tine cultivation (cores harvested, holes filled with topdressing) or aggressive vertical mowing to help maintain macroporosity at the surface, fill voids to smooth the playing surface, and reduce organic matter accumulation (Carrow, 2003).

Topdressing

The objectives of sand topdressing are to 1) dilute thatch accumulation, 2) smooth the playing surface, 3) maintain surface drainage, 4) increase infiltration, 5) increase soil macroporosity at the surface by increasing the sand content of the soil, and 6) increase surface firmness (Figure 6-9).

The goal of topdressing is to keep the crown of the turfgrass plant as close to the soil surface as possible by physically removing organic matter and thatch through cultivation and adding desirable rootzone material to the surface by sand topdressing. Obtaining this goal through proper management enables the turfgrass plant to maximize root development, minimize any disruption in water or air movement, and minimize pest pressure (disease/insect).

The particle size of topdressing material must be compatible with the existing rootzone material. Topdressing materials should have the same particle size distribution as the construction mix or be coarser in texture. Topdressing materials finer in texture than the original construction sand can negatively impact rootzone infiltration rates and result in excessive moisture retention in the topdressing layer. Soil modification with sand of the top 3 inches results in higher infiltration rates and reduced runoff.

Figure 6-9. Topdressing can help maintain good soil physical properties in high traffic areas.

Best Management Practices for Topdressing

- Apply higher rates of topdressing to putting greens in the spring and fall in conjunction with more aggressive forms of cultivation, harvest cores and fill holes with topdressing (Carrow, 2003). Apply lighter, more frequent sand applications (every seven to 14 days) throughout the growing season.
- Laboratory test prospective topdressing materials using [ASTM F1632](#), also known as the Standard Test Method for Particle Size Analysis and Sand Shape Grading of Golf Course Putting Green and Sport Field Rootzone Mixes. Compare the results to USGA guidelines for particle size distribution to determine the suitability as potential topdressing materials.
- Laboratory test prospective topdressing materials using [ASTM F1815](#), also known as the Standard Test Methods for Saturated Hydraulic Conductivity, Water Retention, Porosity, and Bulk Density of Putting Green and Sports Turf Rootzones, to ensure they meet USGA guidelines for hydraulic conductivity.
- Sample existing greens on the golf course (15 to 20 subsamples at 4 inch depth or to the current topdressing layer depth if previously topdressed) and laboratory test using [ASTM F1632](#), and compare with the results with prospective topdressing materials to ensure compatibility.

Plant Growth Regulators

Plant growth regulators (PGRs) are frequently used to reduce clipping yield, improve stress tolerance, and improve turfgrass quality and performance. An additional benefit of using PGRs is a reduction in the use of other inputs (e.g. fertilizers). Plant growth regulators require frequent reapplication during the growing season to maintain consistent growth suppression, but excessive PGR use can result in a number of undesirable side effects. These side effects can include mild discoloration, stressed turfgrass, and segregation of grasses. These effects can be confused with disease, can slow recovery, and can intensify damage from pests and traffic.

The best approach to planning PGR applications is to use growing degree day (GDD) thresholds instead of a calendar-based schedule. Tools are available online for assistance in using GDD information to schedule PGR applications, such as the web-based app [GreenKeeper](#) and Cornell University's [ForeCast](#) web site.

Best Management Practices for PGRs

- Use GDD to plan PGR use.
- Plant growth regulators should not be applied too early or too late in the growing season to avoid stressing turfgrass.

Pesticide Management

Preface

The judicious use of pesticides is generally required, as part of an integrated pest management (IPM) program, to minimize damage to golf course playing surfaces caused by disease, insects, and weeds throughout New England. The term pesticide is inclusive of fungicides, insecticides, and herbicides among others, and is defined by the U.S. Environmental Protection Agency (USEPA) as any substance or mixture of substances intended to prevent, destroy, repel, or mitigate a pest; or any substance or mixture of substances intended for use as a plant regulator, defoliant, or desiccant.

The use of pesticides can pose a risk to human and environmental health. However, the relative risk of pesticides is largely mitigated through governmental regulation of pesticides and their use, and through responsible decision-making and actions of licensed or certified pesticide applicators. When an application is deemed necessary, pesticide selection should be based on effectiveness, toxicity to non-target species, site characteristics, solubility and persistence in the environment, and cost. This chapter focuses on many of these factors, which golf course superintendents should consider to minimize human and environmental risk associated with pesticide use.

Vermont Golf Course Pesticide Permit Program

Since 1991, the Vermont Golf Course Permit Program has reviewed and established guidance for the use of pesticides on Vermont's golf courses with respect to potential impacts on groundwater, surface water, the public, and environmentally sensitive areas. **No pesticide shall be used on any golf course in Vermont without a permit from the Secretary of Agriculture.** The permitting program requires golf courses to submit an Integrated Pest Management (IPM) plan which includes site information describing their use of pesticides, pests controlled, methods to reduce pesticide use, historical pest problems, buffer zones between pesticide applications and sensitive areas and justification for use of pesticides which may be mobile in the environment.

Since 2017 golf courses are also required to have a Nutrient Management Plan (NMP), perform soil testing, nutrient recordkeeping and reporting, and apply fertilizers based upon soil test results and University recommendations.

Questions about Vermont Golf Course Permits should be directed to Matthew Wood, Golf Course Permit Specialist, 802-828-3482, matthew.wood@vermont.gov

The Permit Process

Starting in 2018, the process of permitting golf courses changed, including the annual renewal of all golf course permits. Pesticide active ingredients that were currently approved for use on a course remained approved, and did not need to be re-applied for.

Each Fall, Vermont golf courses must report their fertilizer and pesticide use, and sign the renewal form, to renew their permit for the following year. The pest control products and amounts currently on the permit will be carried forward to the coming year, but if the use of a new active ingredient is desired or an increase in the amount of a currently permitted active ingredient is needed, then the “Vermont Golf Course Dilution Worksheet” below should be used to request that (see Pesticide Information below).

Resources for Golf Course Superintendents

Golf Course Regulations (Excerpt from the Vermont Regulations for Control of Pesticides in Accordance with 6 V.S.A Chapter 87) [Golf Course Regulations \(PDF\)](#) – This version is an update from those handed out at superintendent meetings and includes changes based on feedback from those meetings.

More information can be found on the state's website, by [clicking here](#).

Human Health Risks

Pesticides belong to numerous chemical classes that vary greatly in their toxicity. Toxicity is a measure of a substance’s potential to cause injury, illness, or death. It is characterized through laboratory studies to determine the dose or concentration of a chemical that results in 50% mortality of an animal test population (i.e., lethal dose or LD50). All pesticide labels contain a “Signal Word” (Table 7-1) to characterize their relative risk to human health based on acute toxicity of six studies of oral, dermal, inhalation, and eye and skin irritation (USEPA, 2014).

Table 7-1. Pesticide signal words

Signal Word	Toxicity Level
Danger	Toxicity Category I
Warning	Toxicity Category II
Caution	Toxicity Category III
None required (or Caution as optional)	Toxicity Category IV

However, the risk to human health associated with pesticide use depends on both pesticide toxicity and the level of exposure. Exposure is related to how much an individual is exposed to a pesticide. Thus, the risk of a very highly toxic pesticide may actually be very low, if the exposure is sufficiently small.

To minimize human health risks associated with golf course pesticide use, superintendents should select effective pesticides with lower toxicities, including reduced risk pesticides, and adopt practices that reduce exposure to applicators, staff, and their clientele.

Reduced Risk Pesticides

Special designation is given by the USEPA to pesticides meeting the following criteria: low impact on human health, lower toxicity to non-target organisms (birds, fish, plants), low potential for groundwater contamination, low use rates, low pest resistance potential, and compatibility with IPM (USEPA, 2018). Several reduced risk pesticides are labeled for use in turf (Table 7-2). Some of these have been demonstrated to reduce hazard to golfers due to the reduced toxicity and use rates (Doherty, 2017).

Table 7-2. Reduced risk pesticides labeled for use on golf course turf.

Fungicides	Herbicides	Insecticides
boscalid	penoxsulam	clothianidin
penthiopyrad	carfentrazone-ethyl	chlorantraniliprole
trifloxystrobin	mesotrione	cyantraniliprole
fludioxonil	bispyribac-sodium	fipronil
azoxystrobin		spinosad

List as of June 2018. <https://www.epa.gov/pesticide-registration/reduced-risk-and-organophosphate-alternative-decisions-conventional>.

Re-entry Interval (REI)

This is a period of time in which entry into a pesticide-treated area is restricted. Several pesticides used in production agriculture have specifically stated “re-entry intervals” on the label, preventing workers from entering a treated field for the stated period of time after application unless they use the required personal protective equipment (PPE). The purpose of this restriction is to protect farm workers from exposure to residues of pesticides while they work in the fields. Re-entry intervals are not required following applications made on golf courses, based on current pesticide labels. However, a one-hour re-entry period following golf course pesticide applications reduces worker and golfer pesticide exposure (Putnam et al., 2008; Doherty, 2017).

Research conducted at the University of Massachusetts has demonstrated that pesticide residue transfer from treated turf is greatest within the first hour after

application (Figure 7-1 and 7-2) (Putnam et al., 2008; Doherty, 2017). Thus, pesticide exposure to golfers and staff can be reduced by limiting entrance into treated areas for one hour following an application. However, applying pesticides at night to provide a re-entry period before the following day does not effectively reduce pesticide transfer, and can actually increase pesticide exposure compared with daylight applications (Putnam et al., 2008).

Figure 7-1. Azoxystrobin dislodgeable foliar residues were measured over the first 5 hours following application. Residues of azoxystrobin declined rapidly within the first two hours post application with a 43% reduction of residues 1 hour after application. From Doherty, 2017.

Figure 7-1(b). Imidacloprid dislodgeable foliar residues were measured over the first 5 hours following application. Residues of imidacloprid declined very rapidly with a 4.3-fold reduction within the first hour after application. From Doherty, 2017.

Post-application Irrigation

Irrigating pesticide-treated turf immediately following application can move some pesticide residues from the foliage into the lower canopy, or to the thatch and soil. This practice can reduce dislodgeable foliar pesticide residues 9 to 30-fold compared with turf that is not irrigated after pesticide application (Doherty, 2017). Post-application irrigation may be an effective way to reduce pesticide exposure and may help target some turf pests (e.g., grubs, root pathogens, pre-emergent weeds). It can also delay volatilization of chemicals. However, irrigating treated turf can reduce efficacy of some pesticides, particularly contact materials.

Best Management Practices for Reduce Human Health Risks

- Select the least toxic pesticide with the lowest exposure potential.
- Use Reduced Risk Pesticides when appropriate.
- Restrict staff and golfer entry to pesticide treated areas for at least one hour following application.
- Irrigate pesticides targeting soilborne pests following application to reduce exposure to foliar residues.
- Know the emergency response procedure in case excessive exposure occurs.

Environmental Fate and Transport

Pesticides applied to any environment have the potential to interact with wildlife or migrate into surface and subsurface waters. Environmental implications of a pesticide

can often be determined by the environmental hazards statement found on pesticide product labels. The “Environmental Hazards” statement, found under the general heading “Precautionary Statements,” provides language advising the user of the potential hazards to the environment from the use of the product. The environmental hazards generally fall into three categories: general environmental hazards, non-target toxicity, and endangered species protection.

While pesticides can pose risks to the environment, it is important to recognize that turfgrass systems are particularly well suited to capturing and degrading pesticides due to their high plant density and sub-surface thatch layer (Branham, 2006). In fact, BMPs for minimizing pesticide and nutrient runoff from agricultural fields recommend use of turfgrass between fields and waterways as vegetative filter strips to minimize runoff (Krutz et al., 2005). Pesticides applied to turfgrass systems are often strongly adsorbed to thatch and soil, limiting their movement (Dell et al., 1994; Lickfeldt and Branham, 1995). Moreover, naturally occurring processes including chemical and microbial degradation and photodegradation dissipate pesticides in the environment (Figure 7-3). Environmental fate and transport of pesticides is largely dependent on their physical and chemical properties (Table 7-3). Consideration of these properties can help guide golf course superintendents’ selection of pesticides to reduce environmental impacts.

Figure 7-3. The environmental fate of pesticides diagram.

Table 7-3. Pesticide characteristics associated with increased risk of groundwater and surface water contamination.

Chemical Characteristic	Range for Potential Contamination
Water solubility	greater than 30 ppm (= mg/L)
K_d	less than 5, usually less than 1
K_{oc} (mL/g)	less than 300 to 500
Henry's law constant	less than 10^{-2} atm per m^{-3} mol
Hydrolysis half-life	more than 175 days
Photolysis half-life	more than 7 days
Field dissipation half-life	more than 21 days

Persistence (Half-life)

Pesticide active ingredients are carbon-based molecules that degrade over time. The persistence of any pesticide is characterized by its half-life (DT_{50} or $t_{1/2}$), or the amount of time required for an initial amount to be reduced by half. The half-life of most pesticides is less than 120 days (McCarty et al., 2003). Half-life is independent of the amount of pesticide applied, although the amount applied does affect how many half-life intervals are necessary for a pesticide to be completely degraded. Using pesticides with a shorter half-life can reduce their overall persistence in the environment. Additionally, selecting pesticides with lower use rates, or applying products at lower rates, can also reduce persistence, since less pesticide is initially applied.

Solubility

A chemical's ability to dissolve in water is known as its solubility and is reported as parts per million (ppm), milligrams per liter (mg/L), or grams per liter (g/L). A high solubility denotes a highly soluble chemical. More soluble pesticides have a greater potential of moving in surface or soil water and can be associated with greater risk of runoff or leaching. Pesticides with solubility greater than 30 ppm or mg/L are at increased risk for groundwater and surface water contamination.

Organic Carbon Sorption Coefficient (K_{oc})

The affinity for various pesticides to adsorb to organic matter is commonly expressed as K_{oc} (mL/g). Mature turfgrass stands typically contain a layer of organic matter, referred to as thatch, underlying the canopy. Pesticides with a small K_{oc} value do not strongly adhere to thatch and soil organic matter and are therefore more likely to leach through the soil and reach groundwater. Conversely, pesticides with large K_{oc} values tend to remain near the soil surface, reducing the likelihood of leaching, but can be carried to surface water via runoff or soil erosion.

Pesticide Risk Assessment Tools

USEPA is charged with providing risk assessments of all federally registered pesticides on an ongoing basis. When used according to label recommendations, registered pesticides are expected to have an acceptable amount of risk. Despite this, golf courses that may want to further understand and characterize the pesticides they use can consider one or a combination of several available pesticide risk assessment indices. These tools exist to assess the potential risk of pesticide transport and impact on human and environmental health. They synthesize several characteristics described in the preceding sections to assign a single value to pesticides for comparison. Superintendents may use these values, in addition to efficacy and cost, to select pesticides that further minimize hazards. In all cases, these tools are estimates for how a pesticide may respond in the environment.

Groundwater Ubiquity Score (GUS)

The groundwater ubiquity score is a value used to describe the potential for a pesticide to leach to groundwater based on half-life and K_{oc} plotted on a log-scale (Gustafson, 1989). Pesticides with GUS values greater than 2.8 are considered “leachers,” while those with GUS values less than 1.8 are “non-leachers.” GUS is a convenient tool to assess and compare pesticide leachability. However, in some cases it may overstate (e.g., soils with high organic matter) or understate (e.g., coarse soils) the leaching potential since it does not consider site conditions.

Windows Pesticide Screening Tool (WIN-PST)

[WIN-PST](#) is a free software-based tool developed by the U.S. Department of Agriculture's Natural Resources Conservation Service that can be used to evaluate the potential movement of pesticides in water or eroded soil/organic matter and to estimate the toxicity risk to non-target organisms. It uses soil survey databases with information such as soil type, organic matter content, and water table depth, along with pesticide characteristics, to provide site-specific risk estimates. Users can specify application method, relative application rate (i.e., standard, low, ultralow), and rainfall probability. Long-term human and fish toxicity data and ratings are also included in WIN-PST. Toxicity ratings can be combined with the off-site movement potential ratings to provide an overall estimate of the potential risks from pesticide movement below the root zone and past the target application area.

Environmental Impact Quotient (EIQ)

Environmental impact quotient is a comprehensive pesticide assessment tool that synthesizes risk factors affecting applicator/golf course workers, indirect human hazards, groundwater, and ecological toxicities into a single EIQ value (Kovach et al., 1992). An advantage of EIQ is the ability to compare the potential environmental impact of pesticides based on their formulation and application rates by calculating a “Field Use EIQ” (FUEIQ) (Table 7-4). FUEIQ values can be calculated using the formula below, or

determined online using the “[Calculator for Field Use EIQ.](#)” New York State golf course BMPs (2014) recommend a desirable single application FUEIQ to be less than 25. A value greater than 100 is considered an increased risk.

$$\text{FUEIQ} = \text{EIQ} \times \text{Rate (lbs/acre)} \times \% \text{ Active Ingredient}$$

Using FUEIQ, it is also possible to quantify the cumulative risk of pesticide management programs by totaling all single application FUEIQs over the course of the season. FUEIQ can also be used to characterize pesticide risk of a treated area (e.g., fairway in an environmentally sensitive area) by multiplying the FUEIQ of an application by the total treated acreage. One disadvantage of EIQ compared to WIN-PST is that it does not use site-specific data in its risk assessment.

Table 7-4. Comparison of EIQ and FUEIQ of three contact fungicides applied for dollar spot control in fairway turf.

Active ingredient	% Active ingredient	Application rate	EIQ	FUEIQ
chlorothalonil	54.0%	2.0 fl.oz. / 1,000 ft ²	37.4	110.0
iprodione	23.3%	2.0 fl.oz. / 1,000 ft ²	24.2	61.5
fluazinam	40.0%	0.5 fl.oz. / 1,000 ft ²	23.3	12.7

Best Management Practices for Pesticide Risk Assessment

- Know what and where the target pest is and select an efficacious pesticide and application method.
- Understand pesticide sorption principles so that appropriate decisions can be made.
- Avoid using highly water-soluble pesticides when possible.
- Select pesticides that have a low runoff and leaching potential.
- Before applying a pesticide, evaluate the impact of site-specific characteristics (e.g., proximity to surface water, water table, and well-heads; soil type; prevailing wind) and pesticide-specific characteristics (e.g., half-lives and Koc).
- Identify label restrictions that may pertain to your facility (e.g., additional restrictions for sites with sandy soils).
- Select pesticides with reduced impact on pollinators (see “Pollinator Protection” chapter).
- Select pesticides that, when applied according to the label, have no known effect on endangered species present on the facility.

Pesticide Storage

Storage and handling of pesticides in their concentrated form poses the greatest potential risk to ground or surface waters. For this reason, facilities that store and handle these products must be properly sited, designed, constructed, and operated. Storage facilities should facilitate the secure, dry storage of pesticides; provide safe working conditions for personnel with easy access to PPE; and provide secondary containment of incidental spills due to normal mixing/loading practices and secondary containment of large accidental spills. The following suggestions in this document are offered for consideration, as well more detailed information in [Storing, Mixing and Loading of Pesticides](#) from the Massachusetts Department of Agricultural Resources (MDAR).

Figure 7-4. A self-contained pesticide storage unit.

Storage Location

Storage areas should be located to minimize risk to human health and the environment associated with potential spills, contaminated runoff, or fire. The location should be easily accessible to service vehicles in case of an emergency. Pesticide storage facilities should be at least 400 feet downhill from drinking water supplies and 200 feet from surface water. They should not be placed within a 100-year floodplain, and storm runoff should be diverted around them.

Engineering Controls

Walls and doors: Storage buildings should be built to contain and resist potential fire. Fire rating of walls influences suggested building setbacks (Table 7-5.) Interior walls

should be impervious to pesticides (e.g., painted steel, aluminum, fiberglass). Doors should be lockable, steel (solid core), and set in a steel frame that opens to the outside.

Floors and concrete specifications: Concrete floors with impervious sealant or comparable surface should be used for pesticide storage facilities. Type I or Type II cement is suggested. Epoxy, urethane, polyester, vinyl, chlorosulfonated polyethylene, and polyurea coatings prevent corrosion of floors due to fertilizers and pesticides. Coating efficacy varies and should be selected based on types of products stored in the facility. A continuous sill should surround the floor to contain 125% of the volume of the largest container in storage.

Lights and ventilation: Storage facilities should include enough light to clearly read pesticide labels. A ventilation system should be installed to dissipate potential chemical vapor and ensure a safe workspace. Fans should be wired to turn on with lights and displace six air changes per hour.

Table 7-5. Fire rating and suggested building setback for various wall fireproofing materials. Adapted from: Pesticide Storage Mixing and Loading Guidelines for Applicators. MDAR.

Fire Rating	Gypsum Wallboard†	Hollow Masonry	Solid Masonry	Solid Concrete	Building Setback
1-hour wall	1 layer	3 inch	4 inch	3 inch	50 feet
2-hour wall	2 layer	4 inch	6 inch	4 inch	25 feet
4-hour wall		6 inch	10 inch	6 inch	none

Storage Conditions

Pesticides should be stored in their original container with the label clearly visible. Pesticides within the storage facility should not be exposed to direct sunlight, freezing temperatures, or extreme heat. Flammable materials should be stored in fireproof containment. Separate the fungicides, insecticides, and herbicides within the storage area to prevent unintended usage. Dry pesticides should be stored separately from liquid formulations to prevent contamination in case of leakage. Place pesticide containers within chemical-resistant bins or on shelves with a raised lip to contain leaks. Food, feed, potable water, seed, and personal protective equipment should not be stored within pesticide storage areas.

Best Management Practices for Pesticide Storage

- Store, mix, and load pesticides away from sites that directly link to surface water or groundwater.
- Whenever possible, store pesticides in a lockable concrete or metal building that is separate from other buildings.

- Locate pesticide storage facilities away from other types of structure to allow fire department access.
- Storage facility floors should be impervious and sealed with a chemical-resistant paint.
- Floors should have a continuous sill to retain spilled materials and no drains, although a sump may be included.
- Sloped ramps should be provided at the entrance to allow the use of wheeled handcarts for moving material in and out of the storage area safely.
- Shelving should be made of sturdy plastic or reinforced metal.
- Metal shelving should be kept painted to avoid corrosion. Wood shelving should never be used because it may absorb spilled pesticides.
- Automatic exhaust fans and an emergency wash area should be provided.
- Light and fan switches should be located outside the building, so that both can be turned on before employees enter the building and can be turned off after they leave the building.
- Avoid temperatures less than 40°F or greater than 100°F inside the pesticide storage facility.
- Personal protective equipment should be easily accessible and stored immediately outside the pesticide storage area.
- Place a spill containment kit in the storage area, in the mix/load area, and on the spray rig.

Pesticide Inventory

Pesticides degrade over time. Do not store large quantities of pesticides for long periods. Adopt the “first in–first out” principle, using the oldest products first to ensure that the product shelf life does not expire. Avoid storing pesticides more than two years old and make sure temperatures do not exceed 100°F or drop below 40°F at any time. Utilize computer software systems to record inventory and use. Safety Data Sheets (SDS) for all pesticides on hand should be kept in an easily identifiable location, outside the pesticide storage facility.

Best Management Practices for Pesticide Inventories

- Avoid purchasing large quantities of pesticides that require storage for greater than six months.
- Adopt the “first in–first out” principle, using the oldest products first to ensure that the product shelf life does not expire.
- Ensure labels are on every package and container.
- Consult inventory when planning and before making purchases.
- Control temperature to avoid extreme hot or cold.

Pesticide Mixing/Washing

Pesticide leaks or spills, if contained, will not percolate down through the soil into groundwater or run off the surface to contaminate streams, ditches, ponds, and other waterbodies. One of the best containment methods is the use of a properly designed and constructed chemical mixing center (CMC). These chemically impervious areas prevent seepage of pesticides into soil and facilitate easier clean-up and containment of spills or overflows. Suggestions for CMC building specifications are noted below, and are available in [Storing, Mixing and Loading of Pesticides](#) published by MDAR.

Mixing Pad

Chemical mixing centers should be located at similar distances from drinking water sources and surface waters as pesticide storage facilities, and preferably adjacent to them. An impervious, sealed concrete pad should be constructed to accommodate the sprayer size/weight and tolerate winter freeze/thaw cycles. Edges of the pad should be curbed to contain spills and discharges.

Containment Volume

The CMC should be built large enough to contain a volume 1.25 times the size of the largest spray tank loaded on the pad. Preferably, the area would have a roof to protect the containment area from precipitation. A greenhouse frame covered with a three-year co-polymer film can be a low cost alternative to a roof. In the absence of a roof, the containment volume should be increased to accommodate a two-year, 24-hour storm event (2.9 to 3.6 inches of rain).

Sump Design

The pad should slope to a sump to collect all spills, rinsate, and discharges. Chemically impervious materials should be used for the sump. Minimize dirt, clippings, rocks, and other debris from entering the containment pad and sump. Keep sump clean of solids. A pump should be installed to transfer the liquid collected in the sump to a holding tank for use in subsequent tank filling or applied as a pesticide to appropriate turf areas.

Pesticide Mixing and Handling

Handling open pesticide containers, measuring pesticide materials, or working with pesticide application equipment presents an exposure risk to the handlers and the environment. Applicators and handlers should put on label-recommended PPE prior to opening pesticide packages. All pesticide handling should be restricted to the appropriate storage area or CMC.

Best Management Practices for Pesticide Mixing/Washing Stations

- Loading pesticides and mixing them with water or oil diluents should be done over an impermeable surface, so that spills can be collected and managed.
- The mixing station surface should offer easy cleaning and the recovery of spilled materials.
- Pump the sump dry and clean it at the end of each day.
- Liquids and sediments should be removed from the sump and the pad whenever pesticide materials are changed to an incompatible product (i.e., one that cannot be legally applied to the same site).
- Apply liquids and sediments from the sump as you would a pesticide, strictly following label instructions.
- Absorbents such as cat litter or sand may be used to clean up small spills and then applied as a topdressing in accordance with the label rates or disposed of as a hazardous waste.
- Sweep up solid materials and use as intended.
- Collect wash water (from both inside and outside the application equipment) and use it as a pesticide in accordance with the label instructions.
- The rinsate may be applied as a pesticide (preferred) or stored for use as makeup water for the next compatible application.

Personal Protective Equipment

Based on exposure, pesticide handlers and applicators are at the greatest risk for potential adverse health effects. Exposure to pesticides can be mitigated by practicing good work habits and adopting modern pesticide mix/load equipment (e.g., closed-loading) that reduce potential exposure. PPE statements on pesticide labels provide the applicator with important information about protection.

Best Management Practices for PPE

- Provide adequate PPE for all employees who work with pesticides (including equipment technicians who service pesticide application equipment).
- Ensure that PPE is sized appropriately for each person using it.
- Make certain that PPE is appropriate for the chemicals used.
- Ensure that PPE meets rigorous testing standards and is not just the least expensive.
- Store PPE where it is easily accessible but not in the pesticide storage area.
- Forbid employees who apply pesticides from wearing facility uniforms home where they may come into contact with children.
- Provide laundering facilities or uniform service for employee uniforms.
- The federal Occupational Safety and Health Administration (OSHA) requires employers to fit-test workers annually who must wear tight-fitting respirators.
- Meet requirements for [OSHA 1910.134 Respiratory Protection Program](#).

Pesticide Container Management

The containers of some commonly used pesticides are classified as hazardous waste if not properly rinsed, and as such, are subject to the many rules and regulations governing hazardous waste. The improper disposal of a hazardous waste can result in high fines and/or criminal penalties. However, pesticide containers that have been properly rinsed can be handled and disposed of as nonhazardous solid waste. Federal law (Federal Insecticide, Fungicide, and Rodenticide Act, or FIFRA) and some state laws require pesticide applicators to rinse all empty pesticide containers before taking other container disposal steps. Under federal law (Resource Conservation and Recovery Act, or RCRA), a pesticide container is not empty until it has been properly rinsed.

Best Management Practices for Pesticide Container Management

- Rinse pesticide containers immediately in order to remove the most residue.
- Rinse containers during the mixing and loading process and add rinsate water to the finished spray mix.
- Rinse emptied pesticide containers by either triple rinsing or pressure rinsing.
- Puncture empty, rinsed pesticide containers and dispose of them according to the label.

Emergency Preparedness and Spill Response

Accidents can happen. Advance preparation on what to do when an accident occurs is essential to mitigate the human health effects and the impact on the environment. A spill containment kit containing absorbent materials (e.g., reusable gelling agents, cat litter, clay, soil, or sand), garbage can, and a shovel should be available for small spills. Hydrated lime or bleach can be used to neutralize and clean surfaces where spills occur. Spill containment kits should be easily accessible within the pesticide storage area. Ensure that PPE, a first-aid kit, and eye-wash stations or eye-wash bottles are accessible outside the pesticide storage and mixing area.

An emergency response plan containing actions to take and personnel to contact in the event of a spill or accident should be in place. The plan should include the following information:

- Names and quantities of pesticides in inventory.
- Location of property, including a map and directions (to relay over phone in emergency).
- Names, addresses, and phone numbers of the designated spokesperson, superintendent, and key employees.
- Plan of facility showing pesticide storage locations, flammable materials, electrical service, water supply, fuel storage tanks, fire hydrants, storm drains, and nearby wetlands, ponds, or streams.

- Location of emergency equipment supplies.
- Contact information for fire, police, hospital, pesticide bureau, spill clean-up firm, board of health, and facility owner.

Ensure that copies of the plan are located near the pesticide storage facility and the office and distributed to local police and fire departments. Maintain copies in English and any other language commonly used by employees. Be sure to update the information regularly for local police and fire departments.

Best Management Practices for Emergency Preparedness and Spill Response

- Develop a golf course facility emergency response plan that includes procedures to control, contain, collect, and store spilled materials.
- An inventory of the pesticides kept in the storage building and the SDS for the chemicals used in the operation should be accessible on the premises, but not kept in the pesticide storage room itself.
- Prominently post “Important Telephone Numbers” including CHEMTREC, for emergency information on hazards or actions to take in the event of a spill.
- Ensure an adequately sized spill containment kit is readily available.
- Designate a spokesperson who will speak on behalf of the facility should an emergency occur.
- Host a tour for local emergency response teams (e.g., firefighters) to show them the facilities and to discuss the emergency response plan. Seek advice on ways to improve the plan.

Sprayer Calibration

Properly calibrated application equipment is paramount to mitigating environmental and human health concerns. Sprayer output is dependent on several variables (e.g., speed, nozzle size, pressure). Spray coverage is often reduced at greater application speeds, regardless of nozzle size. To maximize efficacy of pesticide applications, applicators should consider optimization of spray coverage versus efficiency of labor when choosing spray speeds.

Best Management Practices for Sprayer Calibration

- Ensure that the spray technician is experienced, licensed (or certified), and properly trained.
- Minimize off-target movement of pesticides by using properly configured application equipment.
- Properly calibrate all application equipment at the beginning of each season (at a minimum) and after equipment modifications.
- Check equipment daily when in use.
- Use recommended spray volumes for the targeted pest to maximize efficacy.

- Calibration of walk-behind applicators should be conducted for each person making the application to take into consideration their walking speed and other variables.

Figure 7-5. A calibrated sprayer in action.

Sprayers and Nozzles

Various types and sizes of application equipment are readily available. The size of the equipment (tank size, boom width, etc.) should match the scale of the target area. Larger ride-on sprayers are more efficient for large areas, while small walk-behind boom sprayers are well suited for smaller areas. Smaller boom lengths may increase the accuracy of applications, minimizing overspray on non-target areas. Individual nozzle control on global positioning system (GPS) assisted boom sprayers can further minimize overspray of non-target areas and has resulted in 25% less pesticide applied at some golf courses (USGA Green Section, 2016).

Spray nozzle size and design affect the spray drop size. This can be an important factor influencing the potential for drift and off-target movement of pesticides. Smaller droplet sizes can improve the efficacy of some pesticides, although they are more susceptible to drift. Larger droplets are more resistant to drift, although may reduce the efficacy of some pesticides due to reduced coverage. Nozzles designed to encapsulate an air bubble within the droplet (e.g., air induction nozzles) provide a good compromise between drift reduction (larger droplet size) and coverage and efficacy (drop bursts into small drops on impact). Additionally, nozzles designed with a wider spray angle (i.e., 110° versus 80°) enable booms to be set lower to the ground where they are less susceptible to drift.

Best Management Practices for Sprayers and Nozzles

- Use an appropriately sized applicator for the size of area being treated.
- Equipment too large in size requires greater volumes to prime the system. This can result in significant waste that must be properly handled.
- Use wide-angle, air-induction, flat-fan nozzles to minimize spray drift to non-target areas.

Pesticide Record Keeping

Maintaining accurate records of pesticide-related activities (for example, purchases, storage, inventory, applications, spills, etc.) is essential.

Best Management Practices for Pesticide Record Keeping

- Keep and maintain records of all pesticides used to meet legal (federal, state, and local) reporting requirements.
- Use records to monitor pest control efforts and to plan future management actions.
- Use electronic or hard-copy forms and software tools to properly track pesticide inventory and use.
- Keep a backup set of records in a safe but separate storage area.

Pollinators

Preface

Most flowering plants need pollination to reproduce and grow fruit. While some plants are pollinated by wind, many require assistance from insects and other animals. In the absence of pollinators, many plant species, including many of the fruits and vegetables we eat, would fail to survive. In fact, 35% of the fruits and vegetables that make up our diet require pollination by honey bees and other insect pollinators.

The western honey bee (*Apis mellifera*), a very important pollinator in the United States, is maintained in commercial and residential bee hives all around the country. Recent controversies have arisen regarding honey bee health. Some people believe honey bee hives are struggling and that improper pesticide applications are to blame for their decline. Others believe that honey bee colonies are performing at levels similar to the past 20 or 30 years, and that many factors are contributing to any decline in honey bee colony health. The truth is probably somewhere in the middle. Meanwhile, many other insect pollinators, including many bumble bee species, solitary bees, flower flies, and butterflies play a critical role in our food supply.

One thing that everyone agrees on is that honey bee colonies face many stresses, one of which is the use of insecticides in pollinator foraging areas. Other factors that can impact honey bee health are:

- Stress of being moved from one location to another.
- Stress of moving from one crop to another every five to eight weeks for several months at a time, adapting to a new habitat and diet with each move.
- Stress from tracheal mites and *Varroa* mites, both of which invade colonies and compromise the health of the colony.
- Presence of American foulbrood, a fatal disease caused by *Paenibacillus* larvae, that is not a stress-related disease.
- Stress of other pathogens, which are often stress-related, including *Nosema bombi* and *Crithidia bombi*.
- Habitat loss and impact from extreme weather events and climate change.
- Exposure to insecticides applied when bees are foraging.
- Stress from high fructose diet (which is provided as a supplement when honey is harvested from the hive).
- Winter mortality (e.g., from cold temperatures or desiccating winds).

For more on pollinator basics, see the University of Maryland webpage [Pollinator Basics](#).

Pesticides and Pollinators

The purpose of this section is to discuss methods to minimize any possible harmful impact of pesticides (especially insecticides) on honey bees and other insect pollinators. Pesticides are products designed to control pests (e.g., insects, diseases, weeds, or nematodes). Pesticides and other plant health products, including plant growth regulators, surfactants, and biostimulants, are often used in golf course management. The unintended non-target effects of products used in golf course management are of increasing concern. Therefore, pesticide applicators – and the people making the decisions about pesticide applications – must be mindful of the impact that pesticides can have on pollinator species and their habitats.

Pollinator-protection language is found on labels of all pesticides that can be harmful to pollinators. Some insecticides that are particularly toxic to honey bees have a bright yellow, diamond-shaped box (“bee box”) outlining restrictions on applications (Figure 9-1). Several classes of insecticides, including neonicotinoids and pyrethroids, are known to be toxic to honey bees and other pollinators. Toxicity data for several turf insecticides commonly used in the Northeast are summarized in Table 9-1. The data for bees is given in micrograms per bee. Note that several insecticides (including all the neonicotinoids, most of the pyrethroids, chlorpyrifos, and spinosyn) have a honey bee LD₅₀ of 0.01 microgram per bee or less. This means that each of these products has the potential to be harmful to honey bees, and therefore every possible step must be taken to minimize the likelihood of exposure of bees to the product.

THE NEW EPA BEE ADVISORY BOX

On EPA's new and strengthened pesticide label to protect pollinators

PROTECTION OF POLLINATORS

APPLICATION RESTRICTIONS EXIST FOR THIS PRODUCT BECAUSE OF RISK TO BEES AND OTHER INSECT POLLINATORS. FOLLOW APPLICATION RESTRICTIONS FOUND IN THE DIRECTIONS FOR USE TO PROTECT POLLINATORS.

Look for the bee hazard icon in the Directions for Use for each application site for specific use restrictions and instructions to protect bees and other insect pollinators.

This product can kill bees and other insect pollinators. Bees and other insect pollinators will forage on plants when they flower, shed pollen, or produce nectar.

Bees and other insect pollinators can be exposed to this pesticide from:

- Direct contact during foliar applications, or contact with residues on plant surfaces after foliar applications
- Ingestion of residues in nectar and pollen when the pesticide is applied as a seed treatment, soil, tree injection, as well as foliar applications.

When Using This Product Take Steps To:

- Minimize exposure of this product to bees and other insect pollinators when they are foraging on pollinator attractive plants around the application site.
- Minimize drift of this product on to beehives or to off-site pollinator attractive habitat. Drift of this product onto beehives can result in bee kills.

Information on protecting bees and other insect pollinators may be found at the Pesticide Environmental Stewardship website at: <http://pesticidestewardship.org/pollinatorprotection/Pages/default.aspx>

Pesticide incidents (for example, bee kills) should immediately be reported to the state/local lead agency. For contact information for your state/tribe, go to: www.epa.gov. Pesticide incidents can also be reported to the National Pesticide Information Center at: www.npic.orst.edu or directly to EPA at: beekill@epa.gov

Alerts users to separate restrictions on the label. These prohibit certain pesticide use when bees are present.

The new bee icon helps signal the pesticide's potential hazard to bees.

Makes clear that pesticide products can kill bees and pollinators.

Bees are often present and foraging when plants and trees flower. EPA's new label makes it clear that pesticides cannot be applied until all petals have fallen.

Warns users that direct contact and ingestion could harm pollinators. EPA is working with beekeepers, growers, pesticide companies, and others to advance pesticide management practices.

Highlights the importance of avoiding drift. Sometimes, wind can cause pesticides to drift to new areas and can cause bee kills.

The science says that there are many causes for a decline in pollinator health, including pesticide exposure. EPA's new label will help protect pollinators.

Read EPA's new and strengthened label requirements: <http://go.usa.gov/jHH4>

Figure 8-1. The USEPA Bee Advisory Box can be found on new insecticide labels that may pose a risk to pollinators.

Note that no correlation exists between mammalian toxicity and bee toxicity. While several insecticides have very low toxicity to mammals (e.g., dinotefuran, thiamethoxam, or spinosad), each of these products is highly toxic to honey bees. Also, note the considerable variation in honey bee toxicity within some chemical classes. For example, chlorantraniliprole (an anthranilic diamide) is virtually non-toxic to honey bees, while cyantraniliprole is moderately toxic to bees.

Recordkeeping is required by law in most New England states in order to use most pesticides. IPM principles suggest that you keep records of all pest control activity so that you can refer to previous outbreaks to determine what worked or did not work, and to select the best course of action in the future.

Table 8-1. Ecotoxicology of several common turf insecticides in several different animal species.

Insecticide class	Insecticide	Mammal LD ₅₀ mg	Bird LD ₅₀ mg kg ⁻¹	Fish LC ₅₀ mg L ⁻¹	Honey bee LD ₅₀ µg
-------------------	-------------	-------------------------------	--	---	----------------------------------

		<i>kg⁻¹</i>			<i>bee⁻¹</i>
Neonicotinoid	chlothianidin	>500	430	104	0.004
	dinotefuran	>2,000	>2,000	>100	0.023
	imidacloprid	424	152	211	0.0037
	thiamethoxam	>1,563	576	>125	0.005
Pyrethroid	beta-cyfluthrin	77	>2,000	0.000068	0.001
	bifenthrin	54	1,800	0.00026	0.1
	lambda-cyhalothrin	56	>3,950	0.00021	0.038
Organophosphate	chlorpyrifos	64	13	0.0013	0.059
	trichlorfon	212	37	0.7	>0.4
Carbamate	carbaryl	614	>2,000	2.6	0.14
Avermectin	emamectin benzoate	24	23	0.174	0.0035
Spinosyn	Spinosad	>5,000	>2,250	2.69	0.024
Anthranilic diamide	chlorantraniliprole	>5,000	>2,250	>12	>4
	Cyantraniliprole	>5,000	>2,250	>12.6	>0.1

Pesticide Application Practices to Protect Pollinators

Pesticide applicators must make careful decisions about what materials to use and when to apply them to minimize the impacts of pesticides on bees, other pollinators, and beneficial arthropods. While integrated pest management BMPs address decision-making considerations for determining whether to use a pesticide to manage a pest (and which pesticide would be least disruptive to bees and other pollinators), countless other factors must also be considered when deciding on a course of action.

Superintendents must determine what is best for a specific facility based on local agronomics (e.g., turf species and cultivars, fertility practices), local geographic conditions (e.g., underlying soils, slopes, surface water, groundwater), cost of materials and labor, availability of application equipment, expectations of the membership, and budget.

Turf entomologists collaborated to create the national BMPs for protecting pollinators (Larson et al., 2017) listed below that can be implemented at golf facilities to protect pollinators. These BMPs provide guidance for decision-making, but the superintendent – and golfers – must recognize that there often are challenging circumstances that limit a superintendent's options.

Best Management Practices for Pesticide Application Practices

- Before applying a pesticide, scout the area for pest and beneficial insect populations (including pollinators), and only apply a pesticide when a pest damage threshold has been reached. Pest thresholds vary from one part of a golf course to another; for example, little or no damage is typically acceptable on putting greens, while golfers and turf managers are more tolerant of pest activity in roughs.
- Use other pest management approaches (e.g., lures, pheromones, cultural manipulations) to manage pest insect populations.
- When pesticides must be used to manage a pest insect population, select one – when possible – with a lower impact on pollinators.
 - Several classes of insecticides are known to be toxic to honey bees, including neonicotinoids, pyrethroids, carbamates, and spinosyns.
 - Chlorantraniliprole has no activity against bees, ants, or wasps.
 - Granular formulations generally reduce pollinator exposure, compared with a sprayable formulation of the same active ingredient.
 - Apply water after the application to move the residue off the surface and reduce exposure.
- Avoid applying pesticides when plants (including flowering weeds) are in bloom or bees are foraging.
- Whenever possible, schedule pesticide applications early in the morning or late in the evening, when few bees are foraging.
- Mow the area immediately before application to remove blossoms from flowering weeds or use herbicides to reduce weed populations (Larson et al., 2013).
- Avoid applications during unusually low temperatures or when dew is forecast.
- Use spray technology (e.g., drift-reduction nozzles, larger droplet sizes) to reduce off-site drift of a pesticide.
- Remember that systemic insecticides (e.g., neonicotinoids) may be absorbed through the roots of nearby ornamental plants and translocated to flowers, so be very careful to avoid applying pesticides in a way that results in translocation of the active ingredient to flowers of nearby ornamental trees and shrubs.

Pollinator-Related Communication

In addition, several steps can be taken to protect pollinators by increasing communication and interaction with people in the community. Recommendations include the following:

- Consider joining a local beekeeper association to become connected with local educational events and mentoring opportunities.
- Consider setting up a couple of hives within a natural area of the golf course, to be maintained by an interested staff member or possibly a nearby beekeeper seeking another suitable location.
- Check with state or local agricultural and natural resource agencies and obtain a list of registered beekeepers within a three-mile radius of the golf course. Let them know of pending applications that could affect honeybees. This advance

notice enables beekeepers to temporarily close hive entrances, keeping bees inside until pesticides have dried on the foliage.

- Attend workshops or online seminars to learn more about pollinators and other beneficial arthropods.
- Use social media and local news media to educate golfers and the general public about the steps taken to minimize impact on pollinators.
- Invite local master gardeners, garden clubs, or student groups to visit the golf course or host workshops at local garden centers to demonstrate how you use the information on a pesticide label to minimize impact on pollinators.

Figure 8-2. To enhance out of play areas, consider planting a pollinator seed blend to attract pollinators to the course.

Enhancing Pollinator Habitat

Pollinators face challenges related to the loss of natural habitat, as suburban areas encroach into more rural settings. Habitat for pollinators includes foraging habitat and nesting sites. One way to encourage pollinator activity on golf courses is to provide pollinator habitat in non-play areas with a diversity of wildflower species to provide a

variety of food sources. General considerations for pollinator-friendly plantings include the following:

- Plants with a variety of colors.
- Flowers with different shapes and sizes.
- Plants with different flowering times to provide forage throughout the growing season.
- Plants with different heights and growth habits.

Creating pollinator-friendly gardens and native grass or tall meadow areas on the property can provide opportunities for superintendents to reach out to the community. Organizing field trips for primary school-aged children can provide a tremendous opportunity to educate the community about the ecological and environmental benefits of golf courses.

Some pesticide manufacturers have developed pollinator programs and provide flower seed blends that have been developed for different regions of the United States. These include [Operation Pollinator\(Syngenta\)](#), [Bee Care \(Bayer\)](#), [Living Acres Monarch Challenge](#), and [Monarchs in the Rough](#). Many environmental organizations provide resources to identify good native plants to enhance pollinator health, as described in the “Landscaping” chapter. Other simple steps for providing nesting sites for native species can include leaving stems, coarse, woody debris, and exposed patches of sand or well-drained soil in out-of-play areas. In addition, nesting boxes or hollow bamboo sticks can be provided for solitary nesting species.

Figure 8-3. Monarchs in the Rough habitat (left) and a Monarch butterfly caterpillar (right).

Best Management Practices to Enhance Pollinator Habitat

- Plant a diversity of flowering pollinator-friendly plants when renovating out-of-play areas.
- Leave nesting materials and sites in out-of-play areas whenever possible.
- Mow natural or pasture areas just once per year – late in the season when plants are going dormant – to control woody plants or other growth at a time that minimizes effect on pollinators.
- Consider providing man-made nesting sites for solitary nesting species.

Maintenance Operations

Preface

Facilities related to the storage and handling of pesticides, fertilizers, and other chemicals, especially in their concentrated form, pose the highest potential risk to water sources if accidentally released in quantity. Therefore, anyone storing, mixing, or loading potentially hazardous chemicals should treat all leaks, spills, and fires as emergencies and be prepared to respond to these emergencies promptly and correctly. For unintended releases of any chemicals, an emergency plan, spill kit, and first-aid kit should be readily available.

The “Pesticide Management” chapter includes storage- and handling-related BMPs specifically for pesticides. This chapter provides additional guidance for maintenance operations and points out differences between managing fertilizer equipment and pesticide equipment.

Storage and Handling of Fertilizers

Storage facilities that are well designed and well maintained protect people from exposure, reduce the potential of environmental contamination, protect chemicals from extreme temperatures and excess moisture, and, in general, reduce liability concerns and potential environmental risks. The storage area should be secure and provide containment features.

Best Management Practices for Storage and Handling of Fertilizers

- Review groundwater sensitivity information before constructing any fertilizer storage facilities or handling areas.
- Storage facilities should not be located in areas with high probability of flooding.
- Locate dry fertilizer storage buildings or liquid fertilizer secondary containment over away from wells, water supplies, or surface water runoff area.
- Construct storage buildings to prevent seepage or spillage of fertilizer under normal conditions.
- Unless stored in a totally enclosed building, all non-liquid fertilizer materials should be covered and stored within an appropriate secondary containment storage structure.
- Construct liquid fertilizer secondary containment capable of holding 125 percent of the volume of the largest container plus the volume of the butts of all other containers inside the liquid containment area.
- Construct dry storage for secondary containment that is of sufficient thickness and strength to withstand loading conditions.
- Design loading areas to prevent spillage onto unprotected areas and create a proper cleanup area by installing curbed containment.

- Post warning signs on chemical storage buildings, especially near entry or exit areas.
- Storage facilities should be secured and allow access only to authorized staff.
- Replace worn or faulty valves, plugs, and threaded fittings in storage containers.
- Install a backflow prevention device on water supply lines used for fertilizer or pesticide mixing or equipment rinsing.
- Lock valves and shutoff devices while storage containers and facilities are not in use.
- Follow hazard safety rules, worker protection laws, and fire prevention rules while handling and storing fertilizer.
- Apply appropriate sealant to seams and cracks in all storage facilities and load/wash/rinse pad areas.
- Use approved containers designed for and compatible with the fertilizer being stored.
- Shelves should be made of plastic or reinforced metal. Metal shelving should be coated with paint to avoid corrosion. Wood shelving should not be used due to its ability to absorb spilled chemicals.
- Exhaust fans and an emergency wash station should be provided.
- Light and fan switches should be located on the exterior of the storage facility.
- Store liquid materials below dry materials to prevent contamination from a leak.
- Train staff and other management on how to access and use the facility's SDS database.
- Maintain accurate inventory lists.

Equipment Storage and Maintenance

Equipment storage and maintenance facilities should be designed to prevent the accidental discharge of chemicals, fuels, or contaminated wash water from reaching water sources. Properly storing and maintaining equipment also extends the useful life of machines and reduce repairs.

Best Management Practices for Equipment Storage and Maintenance

- Store and maintain equipment in a covered area complete with a sealed impervious surface to limit risk of fluid leaks contaminating the environment and to facilitate the early detection of small leaks that may require repair before causing significant damage to the turf or the environment.
- Seal floor drains unless they are connected to a holding tank or sanitary sewer with permission from the local wastewater treatment plant.
- Store pesticide and fertilizer application equipment in areas protected from rainfall. Rain can wash pesticide and fertilizer residues from the exterior of the equipment and possibly contaminate soil or water.
- Store solvents and degreasers in lockable metal cabinets away from ignition sources in a well-ventilated area. These products are generally toxic and highly

flammable. Never store them with fertilizers or in areas where smoking is permitted.

- Keep an inventory of solvents and Safety Data Sheets (SDS) for those materials on-site but in a different location where they will be easily accessible in case of an emergency.
- Keep basins of solvent baths covered to reduce emissions of volatile organic compounds.
- When possible, replace solvent baths with recirculating aqueous washing units. Soap and water or other aqueous cleaners are often as effective as solvent-based products and present a lower risk to the environment.
- Always use appropriate personal protective equipment (PPE) when working with solvents.
- Never allow solvents or degreasers to drain onto pavement or soil, or to discharge into waterbodies, wetlands, storm drains, sewers, or septic systems.
- Collect used solvents and degreasers in containers clearly marked with contents and date. Schedule collection by a commercial service.
- Blow off all mowing equipment with compressed air to reduce damage to hydraulic seals.

Equipment Washing

Equipment washing should be conducted under controlled conditions in an appropriate contained area with minimal risk to the environment to prevent adverse wash water runoff impacts whenever possible. Equipment washing guidelines and restrictions should be established that reduce the potential for pollutants to reach surface water, or groundwater.

Proper cleaning of equipment helps prevent residues from reaching surface waters, groundwater, drainage pipes, or storm sewers. The residues from washing equipment include grass clippings, soil, soap, oil, fertilizer, and pesticide.

A primary concern when washing mowing equipment is the nitrogen and phosphorus nutrients in grass clippings. Using compressed air to blow clippings off mowers before washing can help reduce the amount of nutrients that enter drains via wash water. The best practice is to have a dedicated wash area with a catch basin to collect remaining grass clippings. Clippings can be collected, then composted or removed to a designated debris area. When formal washing areas are not available, a “dog leash” system using a short, portable hose to wash off the grass at random locations, away from surface waters, wells, or storm drains, is an option.

For equipment with possible pesticide residue, BMPs should be followed to ensure that wash water does not become a pollution source. Captured wash water can be used as a dilute pesticide per label, or it may be pumped into a rinsate storage tank for use in the next application and used as a dilute pesticide per the label.

Best Management Practices for Equipment Washing

- Brush or blow off accumulated grass clippings from equipment using compressed air before washing.
- Wash equipment on a concrete pad or asphalt pad that collects the water. After the collected material dries, collect and dispose of it properly.
- Washing areas for equipment not contaminated with pesticide residues should drain into oil/water separators before draining into sanitary sewers or holding tanks.
- Do not wash pesticide-application equipment on pads with oil/water separators. Do not wash near wells, surface water, or storm drains.
- Use spring-loaded spray nozzles to reduce water usage during washing.
- Minimize the use of detergents. Use only biodegradable, non-phosphate detergents.
- Use non-containment wash water for irrigation.
- Do not discharge non-contaminated wastewater during or immediately after a rainstorm, since the added flow may exceed the permitted storage volume of the stormwater system.
- Do not discharge wash water to surface water, groundwater, or susceptible/leachable soils either directly or indirectly through ditches, storm drains, or canals.
- Never discharge to a sanitary sewer system without written approval from the appropriate entity.
- Never discharge to a septic tank.
- Do not wash equipment on a pesticide mixing and loading pad. This keeps grass clippings and other debris from becoming contaminated with pesticides.
- Solvents and degreasers should be used over a collection basin or pad that collects all used material.

Fueling Facilities

Fueling areas should be properly sited, designed, constructed, maintained, and monitored to prevent petroleum products from being released into the environment through spills or leaks. An aboveground storage tank (AST) is easier to monitor for leakage and is therefore the preferred storage method. Because of the potential for groundwater contamination from a leaking underground storage tank (UST), leak detection monitoring is a critical aspect of UST compliance. Any leaks or spills must be contained and cleaned immediately.

Fueling areas should be sited on impervious surfaces, equipped with spill containment and recovery facilities, and located away from surface waters and water wells. Catch basins in fueling areas should be directed toward an oil/water separator or sump to prevent petroleum from moving outside any containment structure. Floor drains in fueling areas should be eliminated unless they drain to containment pits or storage tanks.

Best Management Practices for Fueling Facilities

- Locate fueling stations under roofed areas with concrete pavement whenever possible.
- Ensure that fueling stations have spill containment and recovery facilities located nearby.
- Develop a record-keeping process to monitor and detect leakage in USTs and ASTs.
- Visually inspect ASTs for leakage and structural integrity.
- Secure the fuel storage facilities and allow access only to authorized and properly trained staff.
- Ensure that fuel tanks and pumps are properly labeled.
- Post "No Smoking" signs near fueling facilities.

Figure 9-1. An above ground fuel tank system.

Waste Handling

Facilities need to regularly review how they handle the disposal of unwanted, expired, or accumulated items, including chemicals, paints, pesticides, tires, batteries, used oils, solvents, paper products, plastic or glass containers, fluorescent light tubes, and aluminum cans. Developing recycling programs reduces waste and minimizes the quantity of waste reaching landfills. In some cases, recycling of some wastes may be required locally, and superintendents should be aware of these requirements.

All packaging from chemicals, their containers, and other wastes should be properly disposed of. Pesticide-specific waste handling requirements are identified on the pesticide label and are discussed in more detail in the “Pesticide Management” chapter.

Best Management Practices for Waste Handling

- Label containers for collecting used solvents, oils, and degreasers.
- Recycle lead-acid batteries. If not recycled, batteries are classified as hazardous waste.
- Store old batteries on impervious surfaces in areas protected from rainfall.
- Recycle used tires, paper products, plastic or glass containers, aluminum cans, and used solvents, oils, and degreasers.
- Provide a secure and specifically designated storage for the collection of recyclable waste products.
- Recycle or properly dispose of light bulbs and fluorescent tubes.

Emergency Preparedness and Spill Response

As discussed in the “Pesticide Management” chapter, enough absorbent material must be available to handle a spill of the largest container in storage areas. Sorbent materials include booms, socks or mini booms, pillows, pads and rolls, and loose sorbents. These sorbent materials may be universal or more specific (such as for petroleum products). Having a readily accessible spill kit is a necessity at any facility where chemicals are used or stored. The spill kit should contain, at a minimum, the following:

- Proper clothing and PPE.
- A supply of neutral absorbing materials that may include activated charcoal, clay, or vermiculite.
- Clean water.
- Class B fire extinguisher for chemical fires.
- Detergent for deactivation of spill site.
- Salvage drum for waste cleanup.
- Cleanup tools such as brooms, shovels, and dust pans.

Best Management Practices for Spill Response

- Develop a golf course facility emergency response plan that includes procedures to control, contain, collect, and store spilled materials.
- Prominently post “Important Telephone Numbers,” including the hotline number for emergency information on hazards or actions to take in the event of a spill.
- Ensure an adequately sized spill containment kit is readily available.
- Designate a spokesperson who will speak on behalf of the facility should an emergency occur.

Sustainable Landscaping in Out of Play Areas

Preface

During play, golf competitors often become immersed in their landscaped surroundings. While care of tees, greens, and fairways will always be the highest priority for golf course superintendents, out-of-play areas are also an important component of superintendents' responsibilities. Landscaped and "non-play" areas help delineate in-play areas and contribute to the overall beauty of the golf course design. They enhance course aesthetics, provide wildlife habitat, and add a natural buffer that moderates external noise. Maintaining these aesthetically pleasing areas as sustainably as possible is economically advantageous and supports the biodiversity of pollinators and other wildlife. Developing or expanding naturalized areas may reduce dependence on water, chemical, and fuel inputs, while allowing more intensive maintenance to be reserved for areas dedicated to play (Lyman et al., 2007; Gross and Eckenrode, 2012).

The substantial acreage of golf course properties provides an ideal opportunity for environmental stewardship and conservation. Vegetated areas with a greater diversity of plant species support wildlife by providing forage and habitat for pollinators and other beneficial insects (Tallamy, 2009). Less intensively managed vegetation (e.g., tall grass and naturalized areas) directly correlates with a higher biodiversity of plants and pollinators (Colding and Folke, 2009; Dobbs and Potter, 2013). Golf courses can contribute to plant and pollinator diversity by expanding natural habitat throughout the course – in the rough and other out-of-play areas, as well as in high-visibility areas, such as the property surrounding the clubhouse and other outbuildings.

Benefits of Sustainable Areas on the Golf Course

An ecosystem with a healthy variety of plants fosters a robust biodiversity of animal and insect species. Plants provide a primary food source and habitat, yield nutrients, improve soil health, and produce oxygen. Golf courses can provide a critical link that connects wildlife corridors by increasing naturally vegetated habitat, including unmown grass and native wildflower out-of-play areas. Benefits of increasing the sustainability of out-of-play areas include:

- Attracting beneficial wildlife, supporting pollinator habitat, enhancing biodiversity, and creating aesthetic interest that provides year-round visual pleasure for golfers on the course (Figure 10-1).
- Providing an option for out-of-play areas that requires fewer non-renewable inputs (fertilizer, water, and gasoline) to maintain.
- Protecting soils, natural vegetative cover, water resources, and water quality.
- Greater carbon sequestration potential than high maintenance areas, due to increased with plant biomass production (Wissman, 2016).

Figure 10-1. Tall grass areas add to the beauty of golf course landscapes.

Sustainable Landscaping Concepts

What is sustainable landscaping? According to the American Society of Landscape Architects, “sustainable landscapes sequester carbon, clean the air and water, increase energy efficiency, restore habitats, and create value through significant economic, social, and environmental benefits.”

Dense, healthy turfgrass plays an important function in sequestering carbon. However, frequent maintenance practices contribute to carbon emission, which diminish the carbon sequestering benefits of turfgrasses. The leading cause of increased carbon dioxide (CO₂) emissions is the direct result of fossil fuel use (Gillette et al., 2011). By reducing frequently mown acreage and expanding sustainable areas that are managed with fewer inputs, golf courses can potentially be valuable net carbon sinks (natural systems that absorb and store carbon dioxide from the atmosphere). Naturalized areas can offset the higher carbon demands of intensively managed, priority areas.

When designing a sustainable landscape, plants are selected for much more than simple aesthetic value. Plants should be selected because they are already adapted to the existing soil conditions, available water, and the microclimate, so additional inputs of irrigation, fertilizer, and soil amendments can be reduced or eliminated. Native plants are prioritized because they have evolved in concert with native wildlife and pollinators,

providing the foundation of local food webs that enable butterflies, birds, and other wildlife to survive. Most herbivorous insects and pollinators are specialists that cannot survive on introduced or exotic plant species.

The population of many beneficial insects and pollinators has declined due to a variety of factors, including loss of natural habitat, lack of forage opportunities, diseases, predatory insect infestations, stress, and exposure to pesticides (Mader et al. 2011). Native plants in the landscape contribute to the restoration of local ecosystems and create conditions that support a wide variety of indigenous, beneficial animal and insect species. Therefore, in naturalized or less intensively managed areas of the landscape, where tolerance of potential pest damage is higher, native plants should be prioritized to support pollinators, food chains, and native ecosystems.

Two distinct approaches to sustainable landscape design are as follows:

Traditional design, which uses native plants as an alternative for introduced or exotic ornamental species in a formal garden, often including mulched landscape beds and lawn areas (Figure 10-2). Required maintenance is the same as any typical garden area, with possibly reduced irrigation if drought tolerant plants are used. This type of design is best suited for priority areas of high visibility around the clubhouse or other out-buildings that provide aesthetic focal points.

Naturalized design, which uses maturing and evolving native plant communities, such as tall grass, meadow, and forested areas. This style is a more viable and cost-effective option in the long term for large out-of-play areas. Required maintenance is consistent with meadows and periphery areas.

Facility managers seeking to conserve water and protect ecosystems on the course can employ a type of sustainable landscaping known as Green Infrastructure (GI). GI is effective and economical and improves the safety and quality of life (USEPA, 2017) through the intentional use of the ecosystem services provided by plants in the managed landscape. GI conserves, restores, or replicates the natural water cycle by reducing and treating stormwater runoff, thus turning a potential pollutant into an environmental and economic benefit. Green roofs, rain gardens, bioswales, cisterns, and permeable pavements are examples of GI. Learn more about how to incorporate GI into the golf course in the fact sheet “Sustainable Landscaping in Out-of-Play Areas on Golf Courses.”

Figure 10-2. A traditional garden design that incorporates native plants.

Sustainable High Visibility Areas

Landscape design on the golf course should meet the needs of the membership, protect the course's environmental resources, and remain economically sustainable. It is important that high visibility areas of the golf course (around the clubhouse and other out-buildings) are aesthetically pleasing focal points that enhance the overall course aesthetics (Figure 10-3). The landscaping around buildings makes a lasting impression on club members and guests, which can influence club membership and bookings for club functions and golf outings, as well as support playability of the course. Sustainable landscaping concepts can be incorporated into these landscaped areas to fulfill both the course's environmental commitment and its aesthetic goals in high-priority areas.

Figure 10-3 Native perennials used in a traditional, formal border planting.

Sound design includes the selection of site-appropriate plant cultivars that permit reduced maintenance to remain healthy and attractive. [National Turf Evaluation Program](#), [Alliance for Low Input Sustainable Turf](#), and [Turfgrass Water Conservation Alliance](#) can provide information on improved cultivars of turfgrasses for non-golf areas

with improved drought tolerance and pest resistance. Whenever new construction or renovation occurs, landscaped areas should be amended to include more native plant material. Native plants are best adapted to the local soils, site conditions, and pests. Incorporating native plants supports a reduced maintenance program that requires less time and expense to maintain. Establishing strong, healthy plants is key for weed management in sustainable landscapes.

Any changes to the landscape design should blend in with existing site features. Changes should be made slowly and with significant investment in membership buy-in. For example, many native plants grow more slowly than the introduced exotic plants common to contemporary landscapes. Therefore, communicating plans and progress to the membership will improve membership response to these changes.

Best Management Practices for Landscaping High-Visibility Areas

- Integrate low-maintenance turf and native plant species into landscape areas around the clubhouse, service buildings, and other out-of-play areas and design these areas for ease of maintenance.
- Consider the soil characteristics, climate, sun exposure, water conditions, and pest possibilities when selecting plants. Select plant material not regularly browsed by deer. (Refer to fact sheet “Sustainable Landscaping in Out-of-Play Areas on Golf Courses” for more information.)
- Group plants with similar watering, pH, and fertilizer requirements together to allow for the most efficient use of resources.
- Select each plant based on its unique contribution to the overall project, including blooming schedules, bark, fruit, texture, and habit.
- Utilize native plants wherever possible, integrating them into the landscape along with annuals to maintain season-long color and aesthetic interest.
- Use plants that will perform well over time. Ensure that the mature height and spread of each plant is considered in the landscape design to avoid the need for excessive pruning or regular replacement. For an immediately full, dense landscape, plant annuals or perennial species that can be relocated or divided as plants mature. Quick-growing, short-lived “filler” plants may also help to temporarily embellish a planting bed as it develops.
- Where feasible, design with drought-tolerant and low-water-use plants.
- Use native drought-tolerant plants around buildings, parking areas, or other appropriate places.
- Where irrigation is necessary, utilize high-efficiency irrigation systems (e.g., drip irrigation) in all landscaped areas for maximum efficiency. If possible, design recycling water features, such as collecting rainwater for graywater use.
- Perform a soil test and analysis when analyzing problems or when renovating landscapes.
- Use organic amendments (e.g., compost, compost tea, or leaf mulch), calibrated as part of the overall nutrient management plan, to build healthy soils, establish beneficial soil organisms, and release nutrients over the long term.

- Where necessary, maintain 2-4 inches of organic mulch over the surface of soil, applied a few inches from the base of trees and plants, to keep soil moist and minimize weeds.
- Minimize the use of impervious surfaces and increase permeable features.
- Replenish groundwater by adding rain gardens, green roofs, bioswales, and other permeable surfaces. Install gravel pathways or borders that permit water infiltration, but have low evaporation potential. • Where possible, recycle, reuse, or use locally sourced materials for plants and hardscapes.

Sustainable Naturalized Areas

Sustainable naturalized areas can help golf superintendents' meet their goals to improve both environmental protection and economic sustainability. While tees, greens, and fairways normally require sufficient irrigation for overall plant health (which contributes to visual impact and recovery from traffic), not all areas of a golf course must be maintained as intensely. In particular, facilities that experience increased seasonal water limitations may consider design alterations to reduce the expanse of maintained turfgrass areas.

Using alternative landscape features in selected areas that do not naturally impact the game of golf can result in substantive water, nutrient, labor, and other maintenance cost savings. They can also restore habitat and increase biodiversity. Conventional landscapes use less than 15 species in an average landscaped lot, while the average undisturbed forest or meadow can support 100 species in the same area. In addition, diverse, multi-storied plantings store more carbon than mown turf areas (Selhort, 2012).

A change in design must be carefully implemented in a manner that does not interfere with game play. While developing a plan to improve and expand wildlife habitat, existing native habitats should be protected and existing natural amenities expanded or enhanced. Retain or restore existing native vegetation, where possible. Where appropriate, existing vegetation should be enhanced through the supplemental planting of native species around tee complexes, out-of-play areas, and water sources. Construct or modify any existing storage ponds with shallow margins (vegetated buffers) planted with native wetland vegetation utilized by many wildlife species. Nuisance, invasive, and exotic plants should be removed and replaced with native species adapted to the site.

Best Management Practices for Sustainable Naturalized Areas

- Manage natural areas to encourage wildlife diversity, by increasing habitat for locally threatened or endangered species, and to provide habitat connectivity by linking natural areas.
- Actively manage open-space areas to support native habitats and avoid introduction and establishment of invasive species.
- Utilize a diverse range of species in plant selection.

- Ensure that the areas selected for low-maintenance modification will not significantly impact the pace of the golf game or game satisfaction. Use of GPS data trackers will correctly identify placement of these landscapes by identifying and delineating areas that are not in play for golfers.
- Use unmown turf as a landscape element to help focus the design of formal areas.
- Allow beneficial “weeds” (e.g., milkweed, which supports the survival of monarch butterflies) to grow and mature in out of the way areas where they will not interfere with integral in-play areas.

Habitat Corridors

Golf courses can make a positive and significant impact on wildlife diversity by creating new habitat corridors, which provide a safe haven for many species while simultaneously enhancing the golfing experience. Corridors are areas of habitat that physically connect plant and animal populations that cannot maintain healthy, genetically diverse populations when highly fragmented by human activities or structures (UC-Davis, 2008).

Best Management Practices for Habitat Corridors

- Establish wildlife corridors that connect areas of habitat, enabling animals to travel and forage for food.
- Corridors should be made as wide as possible and located away from roads, trails, and cart paths, to minimize human interactions with wildlife.
- When establishing or renovating out-of-play areas, include a diversity of pollinator-friendly plants in areas where they will not interfere with routine play.
- Remove invasive exotic plants and replace them with native species adapted to the particular ecological conditions prevalent at the site.
- Protect existing ponds and streams by increasing surrounding vegetative cover height (including turfgrass).
- Incorporate well-adapted, drought-resistant plants, including low-growing ground covers, shrubs, and trees that require little, if any, supplemental irrigation once established.
 - Identify and preserve the habitat requirements (food, water, cover, space) for local wildlife species. Preserve existing areas of critical habitat. Retain riparian buffers along waterways to protect water quality and provide food, nesting sites, and cover for wildlife.
 - Preserve available nesting materials and sites in out-of-play areas when possible.
 - Construct and place birdhouses, bat houses, nesting boxes, or bee houses in out-of-play areas; leave dead tree snags, coarse woody debris, and exposed patches of sand or well-drained soil for nesting and feeding sites, provided they pose no danger to people or property.

- Maintain clearance between the ground and the lowest portion of a fence or wall to allow wildlife to pass, except in areas where animals need to be excluded (BMP-Maryland, 2017).

Figure 10-4. A coyote searches for food in a naturalized area.

Meadows/Tall Grass Areas

Replacing supplemental areas of turf with native vegetation, such as in meadows or tall grass areas, provides essential habitat for many species threatened by encroaching development. A meadow is an area of natural grasses and/or native wildflowers that, over time, becomes self-sustaining. Native meadow plants are resilient, accustomed to the regional climate and can survive adverse conditions. Meadow plants have adapted to the existing soil conditions, water availability, and microclimate challenges. Remediated areas improved by human input, through changes to irrigation, fertilizer, and soil amendments, can successfully be reduced or eliminated, over time.

Meadows that are successfully incorporated into landscape management programs can reduce the burden of some property maintenance expenses. Meadows incorporated into golf environments must be maintained as low-growing and thinly vegetated to give players the ability to easily locate and retrieve balls that have made their way out of the fairway.

Proper site selection, plant selection, site preparation, and maintenance is critical to designing, establishing, and sustaining a flourishing, beautiful meadow (Figure 10-4). Refer to fact sheet “[Sustainable Landscaping in Out-of-Play Areas on Golf Courses](#)” for a list of recommended meadow plants. Most meadow plants prefer full sun. A substantial portion (about 40%) of a meadow should be comprised of grasses (Zimmerman, 2010), in order to sufficiently proliferate between perennial forbs to prevent weed seed germination and development. Time spent on site preparation that eliminates competing vegetation leads to fewer weeds in the meadow in subsequent years. Soil surface disturbance during site preparation should be minimized whenever possible, to prevent unnecessary weed germination at the soil surface. Less disturbance to the site will also maintain soil structure and integrity.

As part of the overall meadow establishment protocol, an effective maintenance plan should be developed before planting and implemented at planting for the successful longevity of the meadow. The initial three years of meadow establishment require both patience and focused effort. During establishment, a nurse crop such as a quick-establishing, clump-forming grass can be used to reduce weed invasion, hold the seed or young plants in place, and protect the soil from erosion.

In the first growing season, perennial meadow plants grow slowly, with an average overall height of 2-6”, depending on the species. Annual weeds will proliferate and grow quickly if given the opportunity. Regular mowing and spot treating weeds can prevent weeds from growing too tall and outcompeting the desired perennials. In the second and subsequent years, the meadow should be mowed annually in late winter or early spring, before the next year’s growth begins.

Best Management Practices for Meadows/Tall Grass Areas

- Select an area for a meadow that receives no less than half a day of direct sunlight to ensure success with sun-loving plants.
- For multi-year health of the meadow, include both short-term species (nurse grasses, annuals, and biennials) and long-term perennial species that take multiple years to establish.
- Select grasses to comprise a substantial portion of the plants to populate the meadow.
- Prepare the site by removing competing vegetation, while avoiding unnecessary disturbance to the soil to maintain soil structure and integrity.
- Where meadows are begun by seed in bare soil areas, utilize an annual “nurse” crop in the first year to aid in establishment.

- Mow every 4 to 6 weeks to a height of 4-6" during the first growing season to control weeds, along with spot treating weeds as needed.
- Mow established meadows annually either in late winter or early spring before the next year's growth begin.

Figure 10-5. A successfully established meadow with thriving grasses and perennials.

Plant Selection

The fundamental principle for the environmentally sound management of landscapes is “right plant, right place.” Proper plant selection is the most important step in designing a sustainable landscape planting. Use a detailed, completed site analysis as described in fact sheet “[Sustainable Landscaping in Out-of-Play Areas on Golf Courses](#)” to select appropriate plants for the site and ensure successful establishment based on sunlight requirements, soil conditions, and water availability. Native plants should be an integral component of the landscape design throughout the course and at key focal points.

Native plants are best adapted to the local soils, site conditions, and pests. The goal of species selection in a sustainable landscape is to maintain as close to a natural ecosystem as practical. Whenever possible, 50-70% of the non-play areas should remain in natural cover (Gross and Eckenrode, 2012). As much natural vegetation as possible should be retained and enhanced through the supplemental planting of native trees, shrubs, and herbaceous vegetation to provide active wildlife habitat. Over time, incorporating native plants not only enhances the ecosystem function of a landscape by supporting a wide variety of indigenous, beneficial animal and insect species, it can also reduce the time and expense spent on maintenance. Planting, or preserving, habitat with native plant species provides the greatest benefit to wildlife and increases

biodiversity on the golf course property. Prioritize the planting of species that provide the greatest benefit to wildlife diversity. For example, native species such as oak and aster best sustain species of native butterfly and moth caterpillars (Table 9-1), while non-native species such as Ginkgo or Zelkova support none. Planting these species will be the most effective means to maintain and improve biological diversity of butterflies, moths, and the higher life forms that they sustain such as birds.

Table 10-1. Species that provide the greatest support to native butterfly and moth caterpillars (Tallamy, 2009).

TREES		PERENNIALS	
COMMON NAME (BOTANICAL NAME)	BUTTERFLY/MOTH SPECIES SUPPORTED	COMMON NAME (BOTANICAL NAME)	BUTTERFLY/MOTH SPECIES SUPPORTED
Oak (<i>Quercus</i>)	534	Goldenrod (<i>Solidago</i>)	115
Black Cherry (<i>Prunus</i>)	456	Aster (<i>Symphyotrichum</i>)	112
Willow (<i>Salix</i>)	455	Sunflower (<i>Helianthus</i>)	73
Birch (<i>Betula</i>)	413	Joe Pye Weed (<i>Eutrochium</i>)	42
Poplar (<i>Populus</i>)	368	Blue Grass (<i>Poa</i>)	42
Crabapple (<i>Malus</i>)	311	Sedge (<i>Carex</i>)	36
Blueberry (<i>Vaccinium</i>)	288	Lupine (<i>Lupinus</i>)	33
Maple (<i>Acer</i>)	285	Rye, Blue Wild (<i>Elymus</i>)	31
Elm (<i>Ulmus</i>)	213	Violet (<i>Viola</i>)	30
Pine (<i>Pinus</i>)	203	Wild geranium (<i>Geranium</i>)	24

Best Management Practices for Plant Selection

- Whenever possible, retain 50-70% of the non-play areas in natural cover.
- Choose each plant based on the soil characteristics, climate, sun exposure, water conditions, and existing wildlife.
- Select more stress-tolerant species or cultivars to manage periodic dry/wet conditions.
- Use plants that will perform well over time. Ensure that the mature height and spread of each plant is accounted for to avoid the need for excessive pruning or regular replacement.

- Select plants that don't require excess care to maintain (deadheading, frequent pruning, etc.).
- Group plants with similar water, pH, and nutrient requirements together to allow for the most efficient use of resources.
- Choose plants that are known to occur together naturally to significantly increase the odds of survival and provide the most benefit to wildlife.
- Select each plant based on its unique contribution to the overall design, including flower blooming schedules, bark, fruit, texture, and habitat.
- Where feasible, leave in place the existing understory (brush and young trees) and native grasses and communicate the value of these natural ecosystems to membership.
- The design should look "natural." Replicate the natural system of layers to create harmony and provide year-round interest: a canopy of large shade trees, a medium understory of large shrubs and small flowering trees, a smaller shrub layer, and an herbaceous layer.
- Group plants in odd quantities (1, 3, 5, 7, 9...) for aesthetic appeal.

Energy Management

General Energy Efficiency Considerations

Energy, in the form of electricity, natural gas, diesel, propane, heating oil, gasoline and other fuels, is a significant expense on the golf course. According to the Golf Course Superintendents Association of America (GCSAA), the average 18-hole golf course uses nearly 450,000 kilowatt-hours in electricity alone (Golf Course Environmental Profile, 2012). At an average New England electric rate of \$0.16/kWh, that's \$72,000 in annual electricity costs. Fortunately, golf course managers have many opportunities to reduce energy consumption in many areas of course operations. Making investments in energy efficiency saves money for the golf course and positions the course to be more resilient to future increases in energy prices or regulatory changes. An energy-efficient golf course is also a good steward of natural resources and can enhance its standing in the community by publicizing its efforts to reduce energy consumption and carbon emissions.

Energy Audit

Golf course managers should consider having an energy audit performed for the golf course as a preliminary step before making large capital investments. An energy audit analyzes the energy use of the facility to uncover areas of greatest potential energy savings, allowing a golf course manager to prioritize energy improvements based on return-on-investment. Qualified auditing firms include those holding the Certified Energy Manager (CEM), Certified Energy Auditor (CEA), or Certified Golf Irrigation auditor certifications. The contract with the auditing firm should be clear with respect to the costs and scope of the audit. Some auditors only look at electrical use, while others may only look at the stationary equipment and not the mowing or maintenance equipment. An irrigation audit may be conducted separately by an irrigation specialist. The golf course's utility company or state energy office is a good source for names of reputable auditors, and many states have programs that provide free or reduced-cost audits or other technical assistance. An energy audit can also identify available incentives and financing to reduce the initial investment of energy efficient equipment.

Establish an Energy Management Plan

Once an energy audit has identified areas of greatest concern the audit's recommendations can be utilized to create an energy management plan with specific goals for reducing energy consumption over time. The manager can prioritize the capital expenditures and make a plan to invest in energy efficient equipment as the budget allows. Management can also ensure that staff members are following best practices for energy efficiency and provide training on energy efficient practices. To track energy consumption, managers can make use of online portals from the electric utility as well as monitoring tools supplied by electronic control systems.

Employee Training

A facilities' employees are on the front lines of energy conservation, as their daily choices can contribute to the facility's energy efficiency. Even simple activities such as turning off lights in empty rooms, following a maintenance checklist to keep equipment clean, and keeping equipment properly calibrated can all contribute to energy savings. Management can consider developing a checklist of employee-led maintenance activities and energy conservation behaviors. Staff training allows the employees to buy in to the energy conservation goals and take ownership of their role in energy management.

Course Management

Pumping and Irrigation

Irrigation is one of the largest energy users on a golf course, with irrigation pumping contributing about 30% of the electricity use in the average course (2015 Golf Course Environmental Profile). Fortunately, ample opportunities exist for energy savings by optimizing the design of the irrigation system, ensuring pumps and other system components are properly maintained, and utilizing automated sensors and controls. Regular monitoring and maintenance, as described in the "Irrigation" chapter, is the key to uncovering leaks, waste, and problems that could lead to expensive repairs and wasted energy in the future. Golf course managers should implement a daily, weekly, and monthly maintenance plan with help from their irrigation designer.

Cart Charging

Golf cart charging can use a lot of electricity. Some of that electric use can be saved by moving the charging time to off-peak hours to reduce demand charges from the utility, as many utilities charge their larger energy users a demand charge for energy used during times of highest electric demand. A golf course with a demand charge can save energy and money by switching certain activities from high-peak times to off-peak times. Typically, off-peak times are early morning and late at night.

Mowing

Conventional commercial lawnmowers use gasoline or diesel fuel. Many innovations in alternative-fuel turf equipment can lower emissions and provide other benefits such as extended life, decreased maintenance, and eliminating the risk of fuel theft or spillage. Alternative-fuel turf equipment has a wide range of price points and features. Golf course managers should thoroughly research the specifications of alternative fueled equipment to make the best decision.

Best Management Practices for Efficient Course Management

- Consider switching golf cart charging to off-peak hours. If it is not possible to switch the entire fleet to off-peak times, see if charging can be staggered to minimize the number of carts being charged in the peak hours.

- New national standards for battery charger energy efficiency took effect in 2018. Consider replacing an older battery charger with a model manufactured according to the new standard to save the most energy.
- Consider solar-charged golf carts. These carts work by using a solar panel on the roof of the cart and can reduce electricity consumption of cart charging by 50% to 75%.
- Compressed natural gas requires less maintenance, extends equipment life, and does not spoil or clog the fuel system during storage.
- Propane has many of the same benefits of compressed natural gas. New propane-powered equipment can be purchased, or some gasoline equipment can be converted to propane using a conversion kit.
- Biodiesel, which can be blended with petroleum diesel without modifying the equipment, reduces emissions. Check with the equipment manufacturer to see if a biodiesel blend is approved for use.
- Commercial electric equipment is powered with rechargeable electric batteries. Recent innovations have improved battery life, enabling extended use of commercial equipment between charges. Solar-powered electric equipment is another recent addition to the market that golf courses can consider.
- Hybrid equipment, using a combination of alternative and traditional fuels, is also available for many fuels and offers improved fuel efficiency and emissions reductions.

Buildings and Amenities

Lighting Lighting is used throughout the golf course in both for interior and exterior spaces. Lighting represents one of the easier cost-effective ways to save energy. In the past decade, light-emitting diode (LED) technology has rapidly advanced while costs for these products have decreased by approximately 90%. LED lighting is quickly making other types of lighting obsolete due to the sharp increase in efficiency, decrease in cost, and long life. LEDs can replace not only indoor lighting, but also older mercury vapor or metal halide exterior lighting.

Clubhouse

In a clubhouse, energy efficiency and water conservation measures can be implemented to save energy, including those associated with kitchen equipment, swimming pools, heating, ventilation and air conditioning (HVAC) equipment, bathrooms, and offices.

Best Management Practices for Building & Amenities

- Pick LED lights that come with at least a three-year warranty and consult third-party listings like the [Design Lights Consortium](#) to evaluate options.
- Install timers or photocells on outdoor lighting and consider the use of motion/occupancy sensors where appropriate.

- Where motion/occupancy sensors are not workable, train staff to turn off lights when not in use.
- When considering a lighting retrofit, prioritize the oldest lights that also have the longest run time (hours in use per day).
- Utilize translucent wall panels to provide natural lighting in areas such as equipment maintenance/storage and irrigation pump houses.
- Consider solar energy and other renewable energy sources to reduce overall electric costs for lighting.
- Look for EnergyStar-certified kitchen equipment such as dishwashers, refrigerators, and walk-in coolers. EnergyStar is a joint program of the U.S. Department of Energy and U.S. Environmental Protection Agency that labels energy-efficient appliances and allows the consumer to easily compare the energy consumption of various equipment.
- Ensure kitchen equipment is clean and in good working order. Dirt and dust build-up can lead to wasted energy use and premature equipment failure, so staff should adhere to a maintenance/cleaning checklist.
- Turn off equipment such as burners and broilers when not in use.
- Ensure seals and gaskets around ovens, steamers, refrigerators, and freezers are aligned properly.
- Heat water to the proper setting (140 degrees Fahrenheit) and insulate hot water lines.
- User proper dishwasher setpoints and operation mode. Set rinse pressure to 15 to 25 pounds per square inch to avoid excess water use.
- Set the wash tank temperature to 160 degrees Fahrenheit and the booster heater setpoint to 180 degrees Fahrenheit in accordance with guidelines from NSF International, an organization that develops standards for public health and safety.
- Run the dishwasher only when full and do not run in manual mode.
- Upgrade to low-flow pre-rinse sprayers. Replace sprayers that take less than 30 seconds to fill a one-gallon pail.
- Use a high-efficiency pool heater and consider the use of a solar pool heating system.
- Ensure pool pumps and motors are properly sized and are the most energy-efficient model available.
- Maintain an appropriate water temperature when the pool is in use and turn down the pool heater when not in use.
- Use a pool cover to decrease evaporation when the pool is closed.
- Add windbreaks (trees, shrubs, fencing) around the pool to further reduce evaporation.
- Consider installing EnergyStar-certified commercial boilers with a thermal efficiency of 94% or greater and a turndown ratio of 5:1.
- Change HVAC filters on a regular basis, typically every one to three months.
- Find an HVAC technician to perform regular check-ups to ensure the HVAC equipment is working properly.

- Consider installing EnergyStar air conditioning equipment, especially if the air conditioner is over 10 years old.
- Use a programmable thermostat in conditioned spaces to reduce heating and cooling costs during periods of low use.
- Properly seal heating and cooling ducts and ensure the ducts are insulated.
- Ensure all new building construction meets current state and federal energy codes
- Ensure that buildings are properly insulated and that leaks are sealed.
- Consider adding advanced digital economizer controls to an existing rooftop HVAC unit. These controls bring in ventilation only when needed, reducing the overall energy consumption of the HVAC unit.
- Consider use of a commercial geothermal or water-source heat pump for heating and cooling. A qualified HVAC technician can inform course managers if this technology is applicable for the golf course's buildings.
- Efficient wood boilers can be an effective way to provide supplemental heat. Burning wood may also eliminate or reduce disposal problems on golf courses that generate wood debris.
- Install low-flow faucets and showerheads.
- Install dual-flush, low-flow toilets.
- Install water-free urinals.
- If the golf course does laundry on the premises, ensure washers and dryers are the most efficient models available. Consider ozone laundry systems as an alternative to large commercial washers. Ozone machines use cold water and ozone gas, instead of hot water and chemicals, to clean and disinfect laundry.
- Look for the EnergyStar label when purchasing office equipment such as computers and photocopiers; set the equipment to power down automatically after a period of inactivity.
- Install energy-efficient vending machines and retrofit older vending machines with a controller that reduces the machine's run time.

Renewable Energy

Maximizing energy efficiency is the first step in reducing a facility's carbon footprint. To further reduce the carbon footprint and reduce energy costs, facilities can invest in renewable energy sources. Some types of renewable energy, such as solar and wind, are highly visible to a golf course's guests and the public and can enhance the golf course's environmental image.

Solar PV

Solar photovoltaic (PV) systems have decreased in price dramatically in recent years, making solar system installation an economically viable option for many golf courses, especially when coupled with federal and state incentives. Some considerations for solar include the size of the system, whether to install a ground or roof-mounted system, and whether to lease or own the system. With multiple companies able to install a solar

project, golf courses should consider the services of a third-party consultant to help evaluate which solar company offers the best terms.

Solar Hot Water

A solar hot water heater can be a cost-effective way to provide hot water for the golf course. A solar hot water heater can cut water heating expenses by 50% to 80% in some instances. Golf courses should check with a reputable installer to ensure the system makes sense for the needs of the course.

Geothermal Heat Pump

A geothermal, or ground-source heat pump uses the Earth's heat in cold weather by drawing up the warmer air from below ground. In warm weather, the heat pump sends warm air back into the Earth to provide cooling. A geothermal heat pump can save 40% to 70% in heating and cooling costs, according to a geothermal industry trade group. Golf courses should check with a qualified heat pump installer to understand whether a geothermal heat pump is a viable option.

Wind

Smaller-scale wind turbines are available for individual facilities to offset some of their electric use. Golf courses interested in wind power should get a professional evaluation of wind energy potential to make sure the wind speed is sufficient to make a turbine economically viable.

Biomass

Biomass is any renewable organic matter that can be used for fuel, with the most common fuel source being biogas created by anaerobic digesters. Another type of biomass heating source is a wood-pellet boiler, which can work in some commercial applications. A golf course that produces a large volume of biomass or organic wastes may find biomass energy generation to be a viable option. Check with a qualified consultant to better understand the costs and benefits of biomass energy.

Funding Resources

The U.S. Department of Agriculture administers the [Rural Energy for America Program](#) (REAP) through its Rural Development office. REAP offers grants of up to 25% of project cost and loan guarantees of up to 75% of the project cost to rural businesses that install energy-efficient or renewable-energy projects. To qualify as rural, a golf course must be located in an area with less than 50,000 inhabitants. Grants range from \$1,500 to \$2,500 for energy efficiency and \$2,500 to \$500,000 for renewable energy. Loans range from \$5,000 to \$25 million.

The Federal Business Energy Investment Tax Credit and Modified Accelerated Cost Recovery System offer [tax benefits](#) to businesses that install renewable energy projects. The 30% tax credit for renewable energy significantly lowers the cost of many renewable energy projects.

The [Section 179D Commercial Buildings Energy Efficiency Tax Deduction](#) provides a deduction of \$1.80 per square foot for installations of lighting, building envelope, and HVAC or hot water systems that reduce the building's total energy use by 50% or more. Facilities can receive a deduction of \$0.60 per square foot for meeting a partial qualification. Tax deductions can be retroactively applied to projects installed since January 1, 2006. Golf course managers should check with their accountants to ensure compliance and can work with a qualified energy consultant to develop the documentation for the tax deduction.

New England states may also have state-based energy efficiency resources and funding opportunities.

****Additional Best Management Practices** (NEW)**

Preface

The Vermont BMP was very well received by the State of Vermont. During an informal meeting between VtGCSA board members and various state agency representatives, there was a suggestion made that we include a BMP for the application of snow mold pesticides. The Additional Best Management Practices section was created in 2022, at the end of the Vermont BMP, as a way for VtGCSA to evolve the Vermont BMP to fulfill the needs of our state representatives.

Snow Mold on Turfgrass

[\(The Vermont Supplement to Ornamental and Turf Manual\)](#)

Snow mold is a recurring problem on fine turf in Vermont and other northern areas. Creeping bentgrass and annual bluegrass are especially susceptible to damage though virtually all cool season species may be damaged when conditions are favorable for disease development. Creeping red fescues appear to be most resistant to the snow molds.

Three types of snow mold are the primary pathogens of turf in Vermont; Gray Snow Mold (GSM) caused by *Typhula incarnata*, Specked Snow Mold (SSM) caused by *T. ishikariensis*, and Pink Snow Mold (PSM) caused by *Microdochium nivale*. Grey snow mold and speckled snow mold together are called as *Typhula* blight. These diseases may occur alone or in combination on turf.

Gray Snow Mold appears as irregularly circular bleached patches of turf up to 2 feet across. Soon after snow melt the diseased areas will be matted and contain white or gray fungal growth on the margins. The occurrence and severity of the disease will vary depending on weather conditions and snow conditions. *Typhula* spp. are worst in winters where lasting snow falls on unfrozen turf. *Typhula* spp. are most active in temperatures between 30°F and 55°F. Gray Snow Mold rarely kills turf. Recovery in home lawn situations is usually complete and can be aided by lightly raking the affected areas in the spring.

Pink snow mold appears as bleached to reddish brown circular patches 1 to 8 inches in diameter. As the snow melts the pinkish is observable on the margins to the infected areas. Infection takes place when temperatures are below 60°F. Disease pressure becomes severe with prolonged periods of cool wet weather such as early spring and late fall. Pink Snow Mold can kill turfgrass in severe infections.

Cultural control methods include managing fertility to avoid lush growth going into the snow mold season. Nitrogen fertility should be managed to allow turfgrass to harden off prior to lasting snowfall. Turfgrass should continue to be mowed in the fall until it stops growing. Care should be taken to avoid compacting snow on turf as well.

Chemical controls on a preventative basis are frequently required for creeping bentgrass turf. Where both snow molds occur together it is frequently necessary to combine contact fungicides with systemic fungicides to obtain adequate control. Specific control recommendations can be obtained from University Extension resources such as UMASS and Cornell.

You can find more information on snow mold by clicking on the following hyperlinks:

[UMASS extension article by M. Bess Dicklow \(2011\) and updated by Angela Madeiras \(2020\)](#)

[Cornell University Plant Disease Diagnostic Clinic Fact Sheet for Pink Snow Mold](#)

[Cornell University Plant Disease Diagnostic Clinic Fact Sheet for Grey Snow Mold](#)

Cultural Management

Snow mold infections can be minimized by utilizing several cultural practices that are geared towards limiting conditions for pathogen's infection and aiding spring-time recovery efforts.

- Although all turfgrass species are susceptible to snow molds, Kentucky bluegrass and fine fescues are less susceptible compared to annual bluegrass, creeping bentgrass, perennial ryegrass, and tall fescues. This information should be favored when planting new grass species in areas that have a history of snow mold infections
- Continue to mow turfgrass until it stops growing, in the fall
- Limit/eliminate late season Nitrogen applications. Use slow-release Nitrogen, in the fall, when possible
- Avoid excessive thatch layers
- Eliminate late season Potassium (K) applications
- Reduce snow compaction from snow mobiles, skiers, etc. when possible
- Avoid creating snow drifts or snowbanks
- When symptoms appear after snowmelt, rake the matted area to allow sunlight penetration and increase air flow in the infected turfgrass to speed up recovery
- Promote new, spring growth with light fertilization

Pink snow mold in un-treated rough (left) and a fairway buffer zone (right)

Grey snow mold under a snow bank (left) and after prolonged snow cover in a treated fairway (right)

Chemical Management

Preventative fungicide control for snow molds should be made in late fall prior to the turfgrass going dormant and being covered by permanent snow. Late fall and early spring snow mold applications may also be needed to control Pink Snow Mold, as snow does not need to be present for a PSM disease infection to occur. You will need to make sure your previous year's Pesticide Report has been submitted early enough for you to receive your new Certified Pesticide Applicator license prior to applying any

spring-time fungicide applications, as you are not allowed to apply pesticides without a current applicator license, which expires every December 31st. A Golf course must also have their Pesticide Use Permit renewed for the current year before any pesticide applications take place there.

Every two years, the University of Kentucky, Rutgers University, and the University of Wisconsin publish a guide that details chemical control of turfgrass diseases. The 2020 version can be [found here](#). To find future versions, you can search Google for "University of Kentucky fungicide efficacy" and there is a good chance the latest version of their research will be at the top of the search results. This guide can be very helpful for choosing a fungicide product(s) for control of snow molds. Their efficacy chart is based upon a summary of current disease research and is a great resource for finding effective fungicides to control snow molds.

- Make any fungicide applications when turfgrass is actively growing, so penetrants can be absorbed into the plant
- Use more than one active ingredient (representing differing modes-of-action) when making application for targeting multiple snow mold species and to help prevent fungicide resistance
- Use of surfactants will enhance fungicide control and allow for better coverage over the plant
- Use of green pigments can aid in early spring green-up and allow for better fungicide coverage over the plant
- Adding seedhead control (Proxy) to snow mold applications may result in better springtime seedhead suppression

Application Timing

Turfgrass will need to be actively growing for most snow mold fungicides to work properly, so one cannot spray them too late in the fall or too early in the spring. Grey Snow Mold requires extended snow cover for infections, so spring-time fungicide applications should be targeting Pink Snow Mold only. Heavy rain events may require a reapplication of fungicides, prior to snow cover, so applying snow mold fungicides prior to a heavy rain event is greatly discouraged and should be avoided at all costs. Cool (less than 60°F) and wet weather can produce Pink Snow Mold infections, so spring-time applications may need to occur to avoid PSM. In most of Vermont, snow mold applications made in early November will help reduce infections for the winter months. Some of the newer snow mold products can help protect turfgrass up to 130 days, so selecting the right product for your course can help create a better spring and golf season.

Best Management Practices for Snow Mold

- Limit late season N and K applications
- Minimize thatch layers in turfgrass
- Continue to mow turfgrass until it stops growing
- Apply any fungicides to actively growing turfgrass, prior to permanent snow cover
- Utilize more than one active ingredient, with different modes-of-action, when applying fungicides
- Utilizing surfactants and green pigments can enhance fungicide efficacy
- Adding seedhead suppressant can enhance spring seedhead suppression
